

Salmon Farming Industry Handbook

2026

Forward-looking Statements

This handbook includes forward-looking statements that reflect Mowi's current expectations and views of future events. These forward-looking statements use terms and phrases such as "anticipate", "should", "likely", "foresee", "believe", "estimate", "expect", "intend", "could", "may", "project", "predict", "will" and similar expressions.

These forward-looking statements include statements related to population growth, protein consumption, consumption of fish (including both farmed and wild), global supply and demand for fish (and salmon in particular), aquaculture's relationship to food consumption, salmon harvests, demographic and pricing trends, market trends, price volatility, industry trends and strategic initiatives, the issuance and awarding of new farming licenses, governmental progress on regulatory change in the aquaculture industry, estimated biomass utilisation, salmonid health conditions as well as vaccines, medical treatments and other mitigating efforts, smolt release, development of standing biomass, trends in the seafood industry, expected research and development expenditures, business prospects and positioning with respect to market, and the effects of any extraordinary events and various other matters (including developments with respect to laws, regulations and governmental policies regulating the industry and changes in accounting policies, standards and interpretations).

The preceding list is not intended to be an exhaustive list of all our forward-looking statements. These statements are predictions based on Mowi's current estimates or expectations about future events or future results. Actual results, level of activity, performance or achievements could differ materially from those expressed or implied by the forward-looking statements as the realisation of those results, the level of activity, performance or achievements are subject to many risks and uncertainties, including, but not limited to changes to the price of salmon; risks related to fish feed; economic and market risks; environmental risks; risks related to escapes; biological risks, including fish diseases and sea lice; product risks; regulatory risks including risk related to food safety, the aquaculture industry, processing, competition and anti-corruption; trade restriction risks; strategic and competitive risks; and reputation risks.

All forward-looking statements included in this handbook are based on information available at the time of its release, and Mowi assumes no obligation to update any forward-looking statement.

Mowi Salmon Farming Industry Handbook

The purpose of this document is to give investors and financial analysts a better insight into the salmon farming industry, and what Mowi considers to be the most important value drivers.

14.4	Branding and product innovation	117
	APPENDIX	118

1 Introduction

Introduction

Salmon is the common name for several species of fish of the family Salmonidae (e.g. Atlantic salmon, Pacific salmon), while other species in the family are called trout (e.g. brown trout, seawater trout). Although several of these species are available from both wild and farmed sources, most commercially available Atlantic salmon is farmed. Salmon lives in the Atlantic and Pacific oceans, as well as the Great Lakes (North America) and other landlocked lakes.

Typically, salmon are anadromous: they are born in freshwater, migrate to the ocean, then return to freshwater to reproduce.

About 80% of the world's salmon harvest is farmed. Farming mainly takes place in large nets in sheltered waters such as fjords or bays. Most farmed salmon come from Norway, Chile, Scotland and Canada.

Salmon is a popular food. It is considered a healthy choice due to its high protein content and high levels of omega-3 fatty acids. It is also a good source of vitamins and minerals.

2 Positioning of Salmon

Positioning of Salmon

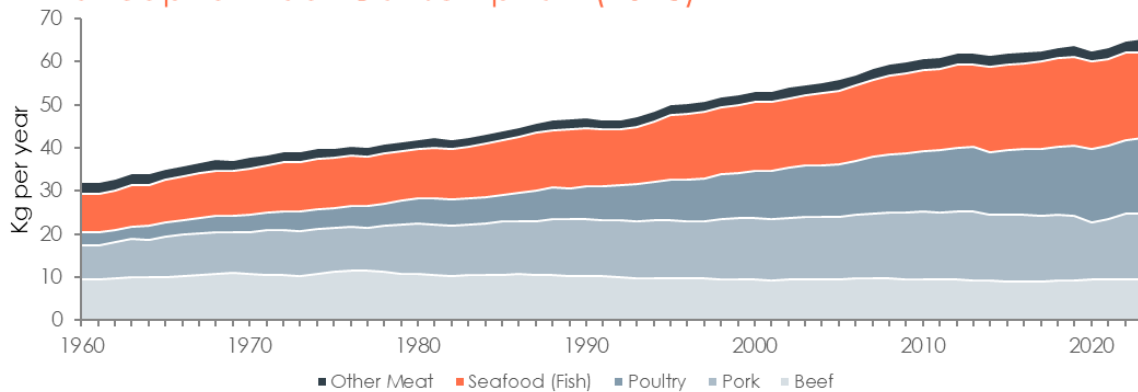

2.1 Seafood as part of global food consumption

Per capita Food Consumption (2023)

The average human ate around 759 kg of food in 2023. Most of this food is produce such as vegetables, fruits, and starchy roots. Animal protein, such as seafood, poultry, pork, and beef, amounts to 9% of the total diet.

Per capita Meat Consumption (2023)

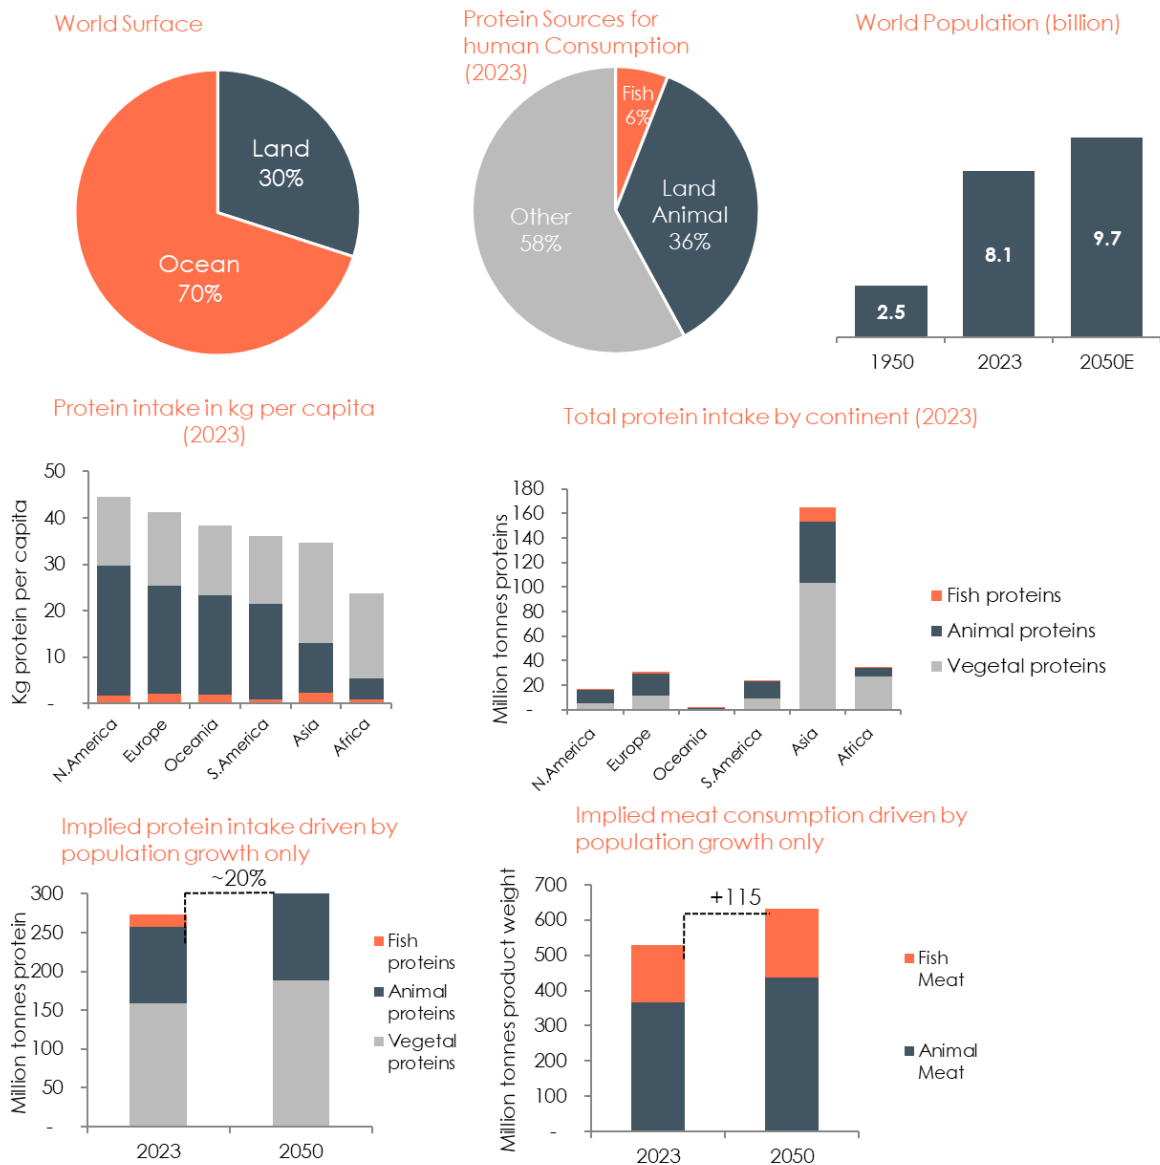

Meat as a food source has gradually become more important. Global per capita supply has more than doubled since 1960, and the seafood segment is a big contributor to this increase.

Source: FAO (2025) FAOstat Food Balance Sheets

Positioning of Salmon

2.2 Seafood as part of overall protein consumption

Although 70% of the Earth's surface is covered by the oceans, fish accounts for only 6% of all protein sources produced for human consumption. The UN estimates that the global population will grow to approximately 9.7 billion by 2050.

Assuming consumption per capita stays constant, this implies a 20% increase in demand for protein. In product weight that means an increased consumption of 106 million tonnes of meat of which 31 million tonnes of fish meat. The UN, however, estimates that demand will actually double. We know that resources for increased land-based protein production will be scarce, so a key question is how the production of protein sources from the sea can be expanded.^{1f}

Source: FAO (2025) FAOstat Food Balance Sheets, UN (2025) World Population Prospects 2025

Positioning of Salmon

2.3 Atlantic Salmon as part of global protein consumption

Most animal protein in our diets comes from fish, poultry, pork and beef, with salmon consumption representing a small portion of global protein consumption.

In 2025, FAO estimated consumption of 176 million tonnes of fish, 151 million tonnes of poultry, 125 million tonnes of pork, and 76 million tonnes of beef and veal.

In contrast, the total consumption of farmed Atlantic salmon was around 2.8 million tonnes (GWT). This corresponds to about 1.9 million tonnes in product weight. If we combine all salmonids (both farmed and wild) it amounts to 3.8 million tonnes (GWT) in 2025.

Source: OECD-FAO (2025) *Agricultural Outlook 2025-2034*, Kontali Analyse

Positioning of Salmon

2.4 Stagnating wild catch – growing aquaculture

Over the past few decades, there has been a considerable increase in total and per capita fish supply. As the fastest growing animal-based food producing sector, aquaculture is a major contributor to this, and its growth outpaces population growth.

Aquaculture has expanded fish availability to regions and countries with otherwise limited or no access to the cultured species. At the global level, since 2016, aquaculture has been the main source of fish available for human consumption. In 2024, this share was 58%, a figure that can be expected to continue to increase in the long term.

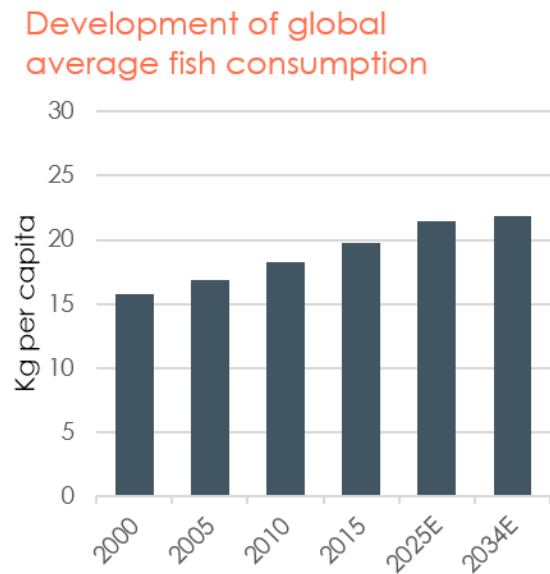

In 2025, aquaculture accounted for 102.7 million tonnes (LW) destined for direct human food consumption, while wild capture accounted for 73 million tonnes (LW). However, fish has been estimated to account for only 7% of global protein consumption (and about 17% of total fish and animal protein supply).

World aquaculture production of farmed aquatic animals has been dominated by Asia, with an 88% share in the last two decades.

Sources: FAO (2025) *The State of World Fisheries and Aquaculture 2025*, OECD-FAO (2025) *Agricultural Outlook 2025-2034*, Kontali Analyse, Mowi

Positioning of Salmon

2.5 Fish consumption

Given the expected production growth of 8% during 2025–2034 and the projected world population growth of 7% over the same period, we will most likely see a global increase in the average fish consumption level.

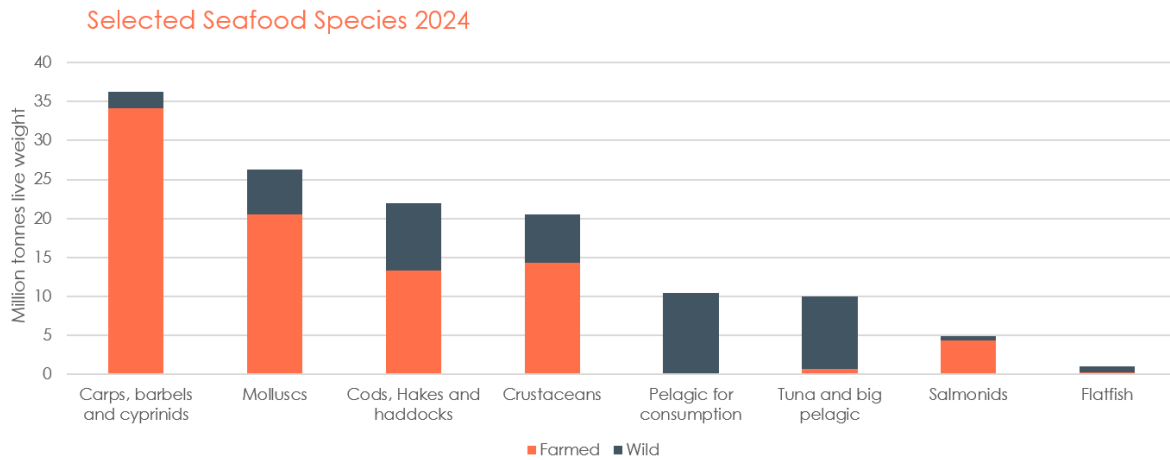

By 2034, per capita fish consumption is estimated to be 21.8 kg (vs. 9.9 kg in the 1960s and 21.4 kg in 2025). This is equivalent to another 16 million tonnes of seafood supply, which aquaculture is estimated to provide.

According to FAO, per capita consumption is expected to increase by 2% in the period 2025–2034. South America and Asia are expected to have the highest growth, whilst negative growth is anticipated in Africa. In general, per capita fish consumption is likely to grow faster in developing countries. However, more developed economies are expected to have the highest per capita consumption.

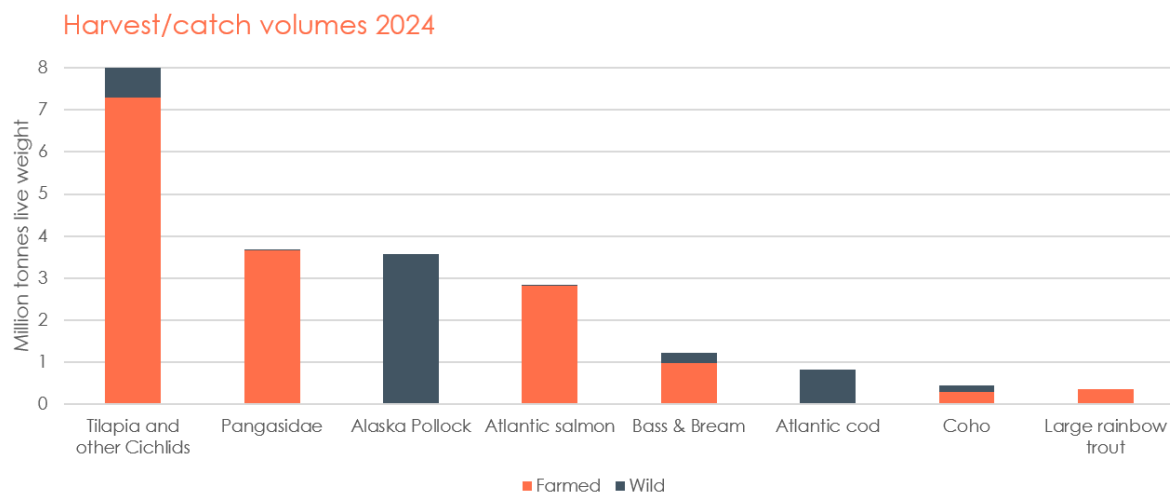

Sources: FAO (2025) The State of World Fisheries and Aquaculture, OECD-FAO (2025) Agricultural Outlook 2025-2034

Positioning of Salmon

2.6 Salmonids contribute 3.7% of global seafood supply

Although several salmon species are available from both wild and farmed sources, almost all commercially available Atlantic salmon is farmed. Even with an increase in production of Atlantic salmon of more than 1,000% since 1990, the total global supply of salmonids is still marginal compared to most other seafood categories (3.7% of global seafood supply). Whitefish is about ten times larger and comprises a much larger number of species.

In 2024, more Atlantic salmon was harvested than Atlantic cod. However, the harvest of Atlantic salmon was only about 25% of that of two of the largest whitefish species, tilapia and pangasidae.

Note: Live weight (LW) is used because different species have different conversion ratios
Source: Kontali Analyse

Positioning of Salmon

2.7 Considerable opportunities within aquaculture

The illustration above shows that Atlantic salmon (sea based) has the highest level of industrialisation and the lowest level of risk compared to other aquaculture species. Atlantic salmon (land based), on the other hand, has proven risky with a low level of industrialisation (scale) to date. The size of the circles indicates volume harvested.

Although Atlantic salmon is relatively small in harvest volume compared to other species, it is a very visible product in many markets due to the high level of industrialisation.

Positioning of Salmon

2.8 Supply of farmed and wild salmonids

© 2026 Kontali. All rights reserved. Not to be reproduced, shared, or distributed without written consent from Kontali

The general supply of seafood in the world is shifting more towards aquaculture as the supply from wild catch is stagnating in several regions and for many important species. Wild catch of salmonids varies between 450,000 and 1,000,000 tonnes GWT, whereas farmed salmonids are increasing. The total supply of salmonids was first dominated by farmed in 1999. Since then, the share of farmed salmonids has increased and farmed salmonids has been dominant.

The total supply of all farmed salmonids was 3.2 million tonnes (GWT) in 2025. The same year, the total catch volume of wild salmonids was approx. one fifth of farmed, with pink, sockeye and chum being the most common species.

Historically, the supply of pink, chum and sockeye have accounted for 97% of the total wild catch volume, whereas pink being the dominated one with approx. 50%.

Positioning of Salmon

2.9 Salmonids harvest 2025

Atlantic salmon: By quantity, the largest species of salmonids. Farmed Atlantic salmon is a versatile product, which can be used for a variety of categories such as smoked, fresh, sushi, as well as ready-made meals. The product is present in most geographies and segments. Due to biological constraints, seawater temperature requirements and other natural constraints, farmed salmon is mainly produced in sea in Norway, Chile, UK, North America, Faroe Islands, Iceland, Ireland, New Zealand and Tasmania.

Small trout: Produced in many countries and most often consumed locally as a traditional dish as hot smoked or portion fish. Small trout is not in direct competition with Atlantic salmon.

Large trout: Produced in Norway, Chile and the Faroe Islands, the main markets are Japan and Russia. Trout is mainly sold fresh but is also used for smoked production.

Coho: Produced in Chile and is mostly used for salted products. It is a competitor of trout and sockeye in the red fish market. Although Russia has increased its import of this fish over the last few years, Japan remains the largest market.

Pink: Caught in USA and Russia and used for canning, pet food and roe production. Since quality is lower than the other species it is a less valued salmonid. The fish is small in size (1.5–1.7 kg) and is caught over a very short time period.

Chum: Caught

in Japan and Alaska. Most is consumed in Japan and China. In Japan, it is available as fresh, while in China it is processed for local consumption and re-exported. Little chum is found in the EU market. The catch varies in quality, and part of the catch is not fit for human consumption.

Sockeye: Caught in Russia and Alaska. It is mostly exported frozen to Japan, but some is consumed locally in Russia and some canned in Alaska. Sockeye is seen as a high-quality salmonid and is used for salted products, sashimi and some is smoked in the EU.

Chinook/King: Small volumes, but highly valued. Alaska, Canada and New Zealand are the main supplying countries. Most quantities are consumed locally. Chinook is more in direct competition with Atlantic salmon than the other species and is available most of the year.

3 Salmon Demand

Salmon Demand

3.1 Global macro trends

The industry is a good fit with the global macro trends, as Atlantic salmon is a healthy, resource-efficient and climate-friendly product produced in the sea.

The global population is growing, resulting in increased global demand for food. The world's population is expected to grow to almost 10 billion by 2050.

The health benefits of seafood are increasingly being promoted by global health authorities. The EAT-Lancet Commission recommends increased consumption of fish, dry beans and nuts as sustainable, healthy protein sources. Farm-raised salmon is rich in omega-3 fatty acids, vitamins and minerals.

Global fisheries are to a large extent fully exploited, meaning the supply of wild fish has limited potential to meet the growing demand for marine protein.

The middle class is growing in large emerging markets, allowing more people to eat different, and more nutritious, protein rich foods, such as fish, meat and eggs. Consumption of high-quality proteins is expected to increase.

Another demographic trend driving shifts in demand is the aging population. Healthy eating becomes especially important as you grow older.

Climate change is the greatest environmental challenge the world has ever faced. Soil erosion is a growing issue for food production, challenging the world to investigate new ways of feeding the population. Concerns about climate change are influencing dietary choices. Increased consumption of fish can reduce global GHG emissions and improve human health.

Source: Ocean Panel (2019) The Ocean as a Solution to Climate Change: Five Opportunities for Action, UN (2025) World Population Prospects, FAO (2025) The state of the world fisheries and aquaculture.

Salmon Demand

3.2 Favourable attributes of salmon

Demand is partly driven by supportive megatrends, but of even greater importance are the characteristics of the product itself.

Salmon is a healthy product and scientifically proven natural superfood. It is nutritionally dense and has a favourable nutritional content.

Salmon appeals to the consumer with its top appetising taste, look, texture and colour. Furthermore, salmon is a versatile product suitable for both traditional and evolving food occasions. It is a good choice for Sunday dinner with the family or at the restaurant, but also a great product for food festivals or just as a snack. Another feature that makes salmon relevant for multiple occasions is that it can be served in many forms, including raw, grilled, cooked and smoked. It appeals to people of all ages as it addresses the health needs of the elderly, while being equally attractive to youngsters.

There is a rising demand for more sustainable food and a willingness to pay for it. The sustainable properties of salmon therefore make the product attractive to consumers.

Salmon Demand

3.2.1 A healthy product

Atlantic salmon is rich in long-chain omega-3, EPA and DHA, which reduce the risk of cardiovascular disease. Data also indicates that EPA and DHA reduce the risk of a large number of other health issues.

Salmon is nutritious, rich in micronutrients, minerals, marine omega-3 fatty acids, high-quality protein and several vitamins, and represents an important part of a varied and healthy diet. FAO highlights that: “Fish is a food of excellent nutritional value, providing high quality protein and a wide variety of vitamins and minerals, including vitamins A and D, phosphorus, magnesium, selenium and iodine in marine fish”.

The substantial library of evidence from multiple studies on the nutrients present in seafood indicates that including salmon in your diet will improve your overall nutrition and may even yield significant health benefits. Considering global obesity rates, governments and food and health advisory bodies around the world are encouraging people of all ages to increase their seafood intake, with particular focus on the consumption of oily fish, such as salmon. The U.S. Department of Health and the US Department of Agriculture recommend an intake of at least 237 grams of seafood per week for Americans in general. The UK National Health Service, the Norwegian Directorate of Health and several other national health organisations recommend eating fish at least twice a week.

Source: Mowi, FAO, WHO, The Norwegian Directorate of Health, Health and Human Services, US Department of Health (2020) *Dietary Guidelines for Americans 2020-2025*

Salmon Demand

3.2.2 Resource-efficient production

Salmon is the most sustainable farmed animal protein alternative

				
Protein retention	28%	37%	21%	13%
Feed conversion ratio ("FCR")	1.3	1.9	3.9	8.0
Edible meat per 100 kg feed	56 kg	39 kg	19 kg	7 kg
Carbon footprint (kg CO ₂ / kg edible meat)	5.1 kg	8.4 kg	12.2 kg	39.0 kg
Water consumption (litre / kg edible meat)	2,000	4,300	6,000	15,400
Monthly mortality	0.7%	2.3%	2.9%	0.3%

To optimise resource utilisation, it is vital to produce animal proteins in the most efficient way. Protein resource efficiency is expressed as "Protein retention", which is a measure of how much animal food protein is produced per unit feed protein fed to the animal. Salmon has a protein retention of 28%, which is more efficient than pork and cattle (see table above). Calorie retention is measured by dividing calories in edible portion by calories in feed. Salmon has a high calorie retention of 25%.

The main reason why salmon convert protein and energy to body muscle and weight so efficiently is that they are cold-blooded and therefore do not have to use energy to heat their bodies. Furthermore, they do not expend energy on standing up like land animals do.

- Edible yield is calculated by dividing edible meat by total body weight. Atlantic salmon has a high edible yield of 73%.
- Feed conversion ratios measure how efficiently the different animal proteins are produced. In short, this tells us the kilograms of feed needed to increase the animal's bodyweight by one kg. Feed for Atlantic salmon is high in protein and energy which accounts for Atlantic salmon's feed conversion ratio being even more favourable than its protein and energy retention when compared with the production of other land animal proteins.
- Edible meat per 100 kg of feed fed is the combination of the FCR ratio and edible yield and presents salmon as giving a favourably high quantity of edible meat per kg of feed fed.

Source: Fry et al (2018) Corrigendum: Feed conversion efficiency in aquaculture: do we measure it correctly? (2018 Environ. Res. Lett. 13 024017)

Salmon Demand

3.2.3 Climate friendly production

In addition to its resource-efficient production, farmed fish is also a climate-friendly protein source. It is expected to become an important solution to providing the world with vitally important proteins while limiting the negative effect on the environment.

According to Blue Food Assessment and SINTEF the carbon footprint of farm-raised salmon is 5.1 kg of carbon equivalent per kg of edible product, compared with 8.4 kg, 12.2 kg and 39.0 kg carbon equivalent per kg of edible product of chicken, pork and beef, respectively. For the consumer, replacing land-based proteins with fish would significantly reduce their personal carbon footprint (daily greenhouse gas (GHG) emissions).

Freshwater is a renewable but limited natural resource, and human activities can cause serious damage to the surrounding environment. Production of farmed Atlantic salmon requires 2,000 litres of freshwater per kg of edible meat, which is significantly less than other proteins.

	Salmon	Chicken	Pork	Beef
Carbon Footprint				
<i>Kg CO₂ / Kg edible meat</i>	5.1 kg	8.4 kg	12.2 kg	39.0 kg
Water consumption				
<i>Litre / Kg edible meat</i>	2,000*	4,300	6,000	15,400

*Total water footprint for farmed salmonid fillets in Scotland, in relation to weight and content of calories, protein and fat.

Source: SINTEF (2020) Greenhouse gas emissions of Norwegian seafood products in 2017, Mekonnen, M.M. and Hoekstra, A.Y. (2010) The green, blue and grey water footprint of farm animals and animal products, SARF (2014) Scottish Aquaculture's Utilisation of Environmental Resources

Salmon Demand

3.3 Relative price development of protein products

Relative price development 2016-2025

Prices for most proteins have increased over the past decade, with a particularly sharp rise during 2021 and 2022. In 2023, prices declined across most categories, except for salmon. Since then, price developments have diverged: salmon prices were broadly flat in 2024 before declining in 2025, while other proteins continued to increase. As a result, salmon has seen a more moderate price development relative to competing proteins in recent years.

Relative price differences indexed to salmon

Salmon has historically always been a rather expensive product on the shelves.

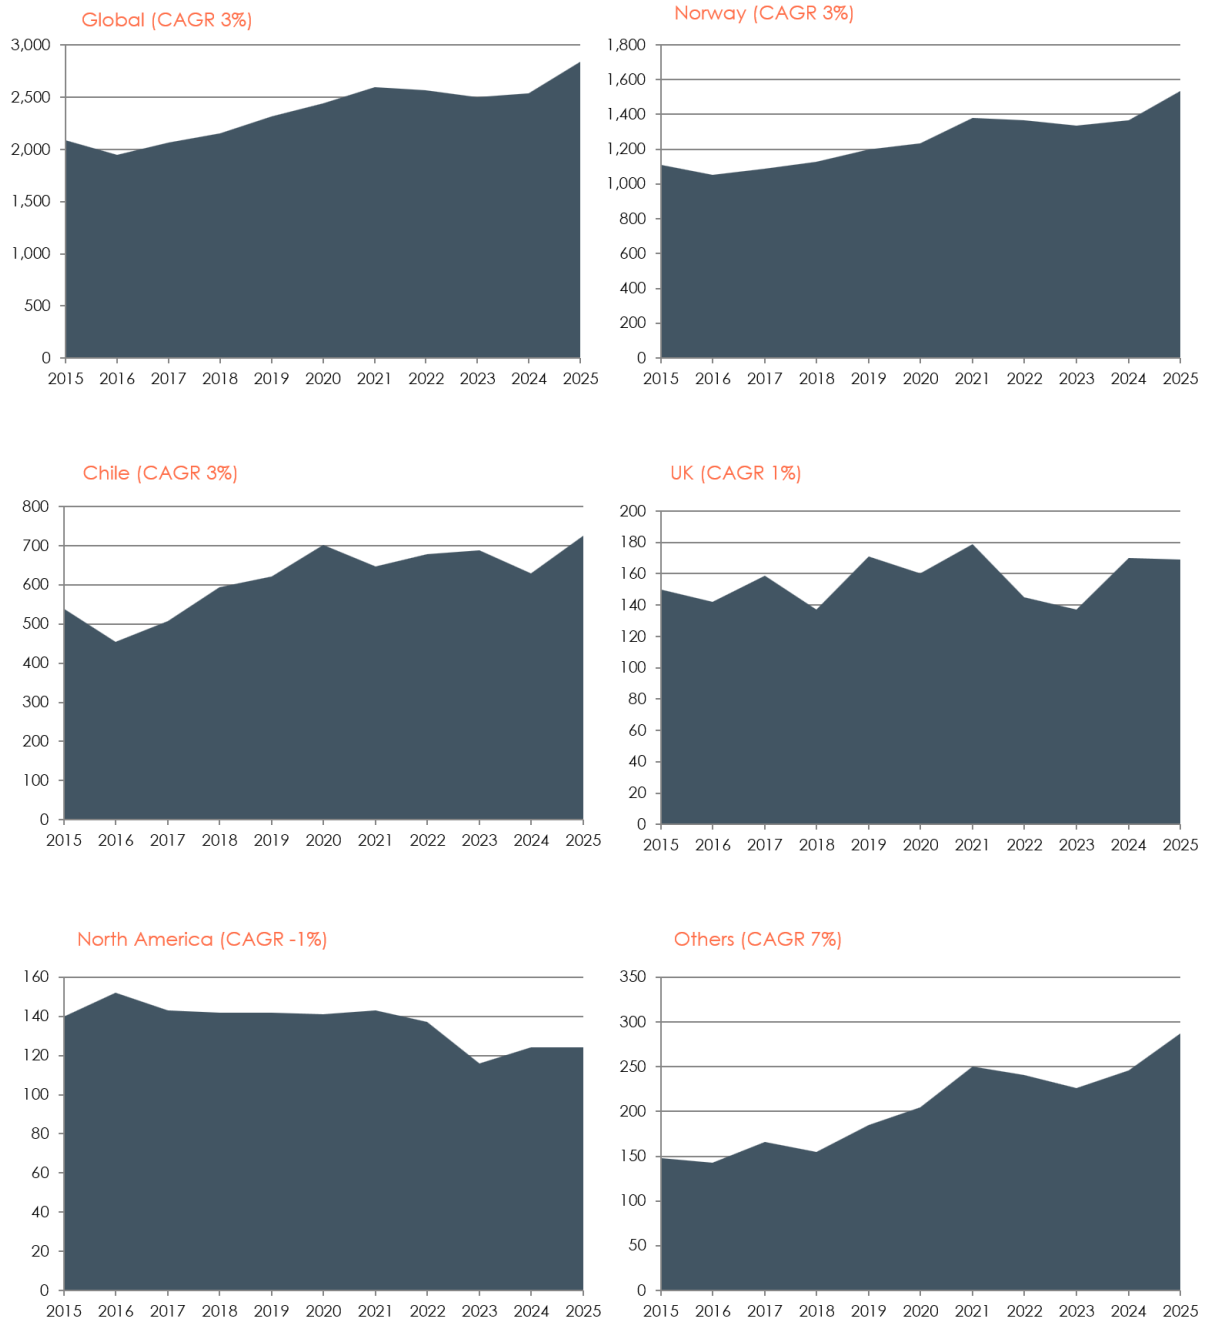

Source: IMF Primary Commodity Prices (2025). Beef = Australian and New Zealand beef import price (I: ANZBIP), Lamb = lamb price (I: LP), Pork = US swine price (I: USSPZRXF), Chicken = US chicken spot price (I: USDCSP), Salmon = Norway salmon price (I: NSP)

4 Salmon Supply

Salmon Supply

4.1 Total harvest of Atlantic salmon 2015–2025

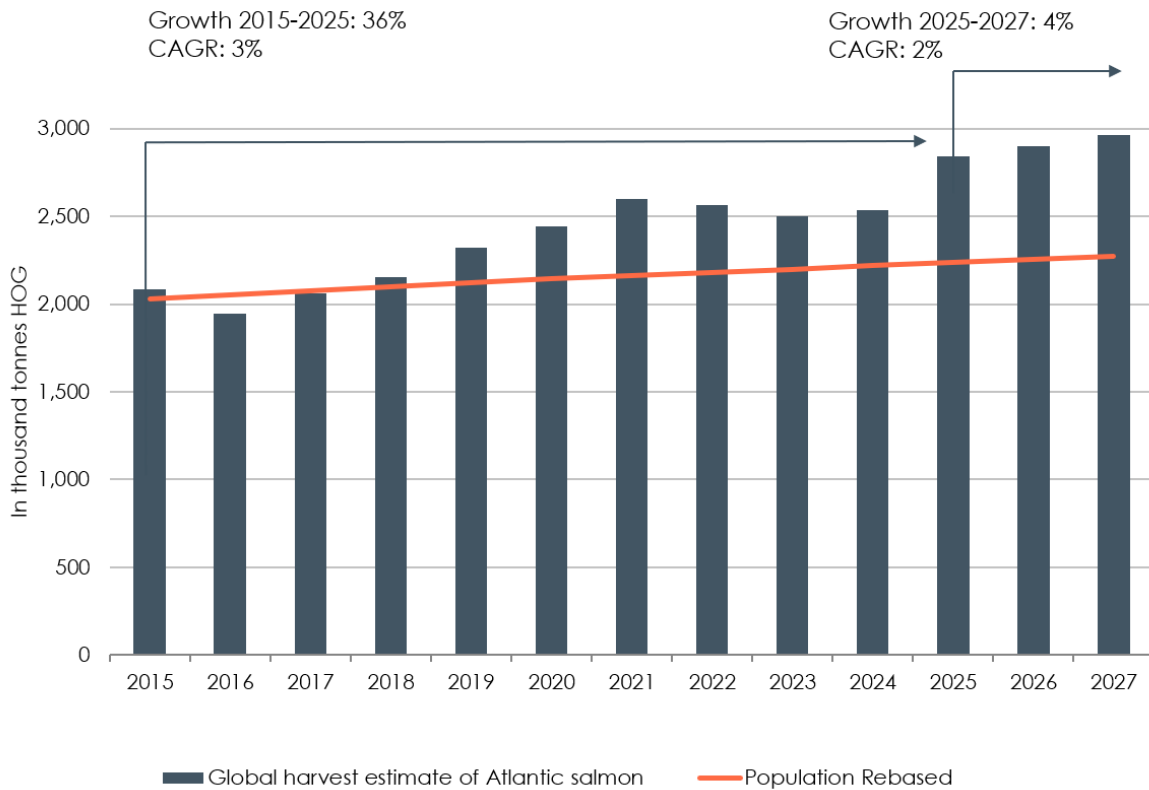

© 2026 Kontali. All rights reserved. Not to be reproduced, shared, or distributed without written consent from Kontali

CAGR	Global	Norway	Chile	UK	North America	Others
2005-2025	5%	6%	4%	2%	1%	9%
2015-2025	3%	3%	3%	1%	-1%	7%
2025-2027E	2%	1%	1%	3%	1%	10%

Note: Figures are in thousand tonnes GWT and "Others" includes the Faroe Islands, Ireland, Tasmania, Iceland and Russia

Salmon Supply

4.2 Diminishing growth expectations

Supply of Atlantic salmon has increased by 608% since 1995 (annual growth of 7%). Annual growth in the period 2015–2025 was 3%. Mowi expects annual industry growth to remain relatively stable at 2% CAGR from 2025 to 2030.

The background for this trend is that the industry has reached a production level where biological boundaries are being pushed. It is therefore expected that future growth can no longer be driven only by the industry and regulators as measures are implemented to reduce its biological footprint. This requires progress in technology, development of improved pharmaceutical products, implementation of non-pharmaceutical techniques, improved industry regulations and intercompany cooperation.

Too rapid growth without these measures in place adversely impacts biological indicators, costs, and in turn output.

Note: Mowi does not provide guidance of industry supply except for guidance depicted in quarterly presentations.

Source: Mowi, Kontali Analyse, UN (2025) World Population Prospects.

Salmon Supply

4.3 Few coastlines suitable for salmon farming

The main coastal areas adopted for salmon farming are depicted on the above map. The coastlines are within certain latitude bands in the Northern and Southern Hemispheres.

A key condition is a temperature range between 1°C and 20°C. The optimal temperature range for salmon is between 8°C and 14°C.

Salmon farming also requires a certain amount of current to allow a flow of water through the farm. The current must however be below a certain level to allow the fish to move freely around in the sites. Such conditions are typically found in waters protected by archipelagos and fjords, which rules out many coastlines. However, offshore farming is an emerging approach. Offshore farms are positioned in deeper and less sheltered waters, where ocean currents are stronger than they are inshore, and they therefore require more robust cages.

Certain biological parameters are also required to allow efficient production. Biological conditions vary significantly within the areas adopted for salmon farming and are prohibitive in certain other areas.

Political willingness to permit salmon farming and to regulate the industry is also required. License systems have been adopted in all areas where salmon farming is carried out.

Land-based salmon farming (full-cycle) has attracted increased investments in recent years. To date, only limited volumes have been harvested on land, however, this could change going forward as new production technologies continue to mature.

5 Sustainable production

Sustainable production

5.1 UN's Sustainable Development Goals

The SDGs, which were agreed by all 193 UN member states in 2015, guide governments, civil society and the private sector in a collaborative effort for change towards sustainable development. Out of the 17 SDGs, the industry can contribute significantly to at least ten: good health and well-being; gender equality; decent work and economic growth; reduced inequalities, sustainable cities and communities; industry, innovation and infrastructures; responsible consumption and production; climate action; life below water and partnerships for the goals.

Sustainable production

5.2 Environmental impact of aquaculture

It is important first to understand the impact of aquaculture on the environment in order to become even more sustainable.

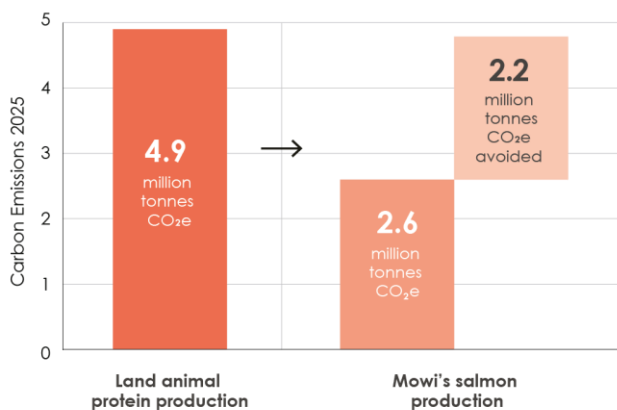

Carbon footprint

Fish farming is among the most climate-friendly forms of animal husbandry. According to the Blue Food Assessment (Environmental performance of blue foods, Gephart et al., 2021) the carbon footprint is only 5.1 kg of carbon equivalent per kg of edible product, compared with 8.4 kg of carbon equivalent per edible kg of poultry, 12.2 kg per edible kg of pork and 39.0 kg per edible kg of beef.

By replacing land animal protein production with farmed salmon, significant CO₂ emissions are avoided. Assuming that global salmon production replaced a mix of poultry, pork and beef production in 2025, 2.2 million tonnes of CO₂ emissions were avoided.

Avoided GHG Emissions

2.2 million tonnes CO₂e emissions are avoided annually by replacing the corresponding amount of land animal protein production.

Genetic changes in wild salmon

Most escaped farmed salmon disappear into the open sea. They are likely to die from starvation, disease or predation. Still, some survive after escaping and migrate into the rivers each year, posing a risk of genetic changes to wild salmon populations.

Source: SINTEF (2020) Greenhouse gas emissions of Norwegian seafood products in 2017, Institute of Marine Research (2026) Risk assessment of Norwegian fin fish aquaculture 2026
Note: The carbon footprint used for land animal protein production was calculated by starting to convert the global production volumes of Atlantic salmon in 2025 to edible yield (using a 73% conversion), then calculating the carbon footprint of that volume originating from animal protein mix. This was done by using a mix of consumption (OECD, 2020) of 40% chicken, 38% pork and 22% beef and the reported GHG emissions from SINTEF 2020.

Sustainable production

The Institute of Marine Research considered four out of 13 production areas in Norway to be at high risk for further genetic changes. Five production areas are considered to be at moderate risk, and three production areas are considered to be at low risk.

Environmental effects of discharges of dissolved nutrients

Dissolved nutrient salts are released into coastal waters by population (sewage), industry, agriculture and aquaculture. In aquaculture, when salmon eat, dissolved nitrogen and phosphorus will be released via the gills and also a smaller proportion in the form of urea. Even though increased concentrations of dissolved nutrients in coastal waters may cause adverse ecosystem changes, the risk of regional environmental impacts as a result of dissolved nutrients from fish farming is considered low in all production areas according to the Institute of Marine Research.

Environmental impact on the seabed as a result of particulate organic emissions

Open pens release organic particles directly into the environment in the form of faeces from the fish and feed that is not eaten. Such discharges can affect the environment to a greater or lesser extent around the fish farm. However, the emissions mainly consist of easily degradable compounds, the impact is reversible, and the seabed can fully regenerate over a few months to a few years. Farmers are obliged by law to monitor the seabed continuously in accordance with NS 9410 or other national regulations, so that the environmental impact of aquaculture is within acceptable limits. If the environmental impact on the seabed is not acceptable, the site may be followed, production reduced or the site reallocated to a different location.

Based on data from today's monitoring system, the condition of soft-bottom sites is considered low risk in 9 of the 13 production areas, whereas 4 production areas are considered moderate risk in Norway. The risk of unacceptable environmental impacts from particulate organic emissions is low. As of today, there is no adequate monitoring of hard-bottom sites, and these have therefore not been evaluated.

Mowi measures the potential impact of organic loading on the seabed according to national seabed quality standards. Results show that, on average, 96% of its sea sites surveyed in 2025 have a minimal impact on faunal communities and/or sediment chemistry near to the fish pens, which is up from 89% in 2024.

Environmental effects on non-target species when using medicine

Sea lice belong to the animal group of crustaceans, and medicines that treat sea lice can potentially affect other species.

There are differences in the way treatments may affect non-target species. Bath treatments may have a short-term effect, while oral treatments may affect non-target species over a longer period of time. Bath treatments include hydrogen peroxide, azamethiphos, cypermethrin and deltamethrin, and the treatment takes place either directly in the pen or in a well boat. If treatment is done in pens, the bath treatment is released directly into the sea.

Source: Institute of Marine Research (2026) Risk assessment of Norwegian fin fish aquaculture 2026, Mowi

Sustainable production

When the treatment takes place in a well boat, the bathing agent is released while the vessel is in motion. However, purification systems designed to remove the medicines used in well boat-delivered bath treatments are being introduced to the market. The oral treatments considered are diflubenzuron, teflubenzuron and emamectin, and a proportion of these can be released to the environment via feed and faeces.

The Institute of Marine Research's risk assessment is a comprehensive assessment and emphasises, among other things, total consumption, toxicity and occurrence in the environment in Norway. Of the treatments considered, azamethiphos and emamectin are considered to have low risk, while hydrogen peroxide, cypermethrin, deltamethrin, diflubenzuron and teflubenzuron are considered to have moderate risk. However, the number of prescriptions was highest in the years 2014 and 2015, respectively 3,477 and 3,285, whereas for 2018 this was reduced to 501. Overall, this presents a significant reduction in the environmental risk.

Mowi only uses licensed medicines when other measures are not sufficient or when fish welfare may be compromised. In 2025, 88% of sea lice treatments were non-medicinal in Norway, compared with 12% in 2015, showing the significant reduction in the use of medicines to manage sea lice, itself made possible by the increased use of non-medicinal tools.

Fish welfare

In Norwegian farm pens, there is a maximum of 200,000 fish per pen at any given time. These are individuals which, according to the Animal Welfare Act, have the right to be kept in an environment that provides good welfare based on species and individual needs, and the opportunity for stimulating activity, movement, rest and other natural behaviour. Farmers must also ensure that feed is of good quality and meets the fish's needs, and that the farmed fish is protected against injury, disease and other hazards. The farmed fish must be robust enough to withstand farming conditions, and they should not be subjected to unnecessary stress.

The challenges in the north of Norway are primarily related to low temperatures and bacterial wound infections, while Western Norway has challenges with PD and injuries in connection with lice treatment.

Survival rate is commonly used as a measure of animal health and welfare. Improved survival can be achieved through good husbandry and management practices, vaccination etc. In 2025, the monthly survival rate measured on fish numbers and based on GSI definition* increased in seawater (99.3%) and was kept stable at the same levels for freshwater (99.1%). This survival rate measured in accordance with GSI methodology is suitable for comparisons across companies applying the same methodology.¹

* reported in accordance with the Global Salmon Initiative (GSI) methodology:
(total # mortality in sea last 12 months / (closing # of fish in sea last month + total # mortality in sea last 12 months + total # harvested last 12 months + total # culled fish in sea) X 100)
Source: Institute of Marine Research (2026): Risk Assessment of Norwegian fin fish aquaculture 2026, Mowi, Barentswatch

Sustainable production

Monthly Survival Rate*

	 Atlantic salmon	 Chicken	 Pork	 Beef
Monthly survival rate*	99.3 %	98.8 %	99.5 %	99.8 %

The survival rate is the complement of the mortality rate.

An alternative calculation of monthly mortality rate, which is simpler and better reflects how the companies themselves and various governmental bodies monitor mortality, is to measure the number of mortalities relative to the opening biomass number. The monthly numbers may be aggregated either per year (annual mortality) or per generation. Mowi refers to this as the industry definition of mortality, as opposed to the GSI definition described above. Measured in accordance with the industry definition, annual mortality in seawater for Mowi Farming, i.e. across all seven farming countries, was 16.8% in 2025 (15.9% in 2024).

Mortality rates vary from country to country and from region to region depending on e.g. environmental conditions such as temperatures, weather conditions, oxygen levels, prevalence of algae and plankton etc. Mowi's best-performing region with regards to mortality is the Faroes with 8.6% annual mortality in 2025. In the largest Farming entity, Mowi Norway, annual mortality was 14.6% in 2025, i.e. better than the overall group figure.

Monthly Mortality Rates

Measured for the complete production cycle (freshwater and seawater), the monthly average mortality rate for Mowi Norway is 0.7%, i.e. lower than for pig (2.9%), chicken (2.2%) and lamb (1.5%). However, because of the salmon's long production cycle of up to three years in total, the nominal cycle mortality rate for salmon is higher than for all of these animals. Also note that in the wild, mortality rates for salmon range from 65% to 95%, i.e. significantly higher than for farmed salmon.

Sustainable production

The salmon is a so-called R-strategist producing a high number of reproductive cells, aiming for at least a few offspring to survive. This contrasts with so-called K-strategists, which produce a low number of reproductive cells. This means that from nature's side, reproductive biology and mortality rates are very different for salmon than for most land farmed animals. This, combined with the significantly longer production time, represents a challenge when comparing mortality rates with other farmed animals. That being said, Mowi puts great emphasis on reducing mortality as much as possible. This is important for many reasons, including fish welfare. Also, from a financial point of view, mortality represents a pure loss.

Industry mortality rates have been relatively stable for the last thirty years, although Mowi saw an improvement in 2025 vs. 2024. However, we expect that our ongoing implementations of postsmolt, as well as shielding technologies (such as submerged pens and closed-containment systems), lasers and other Mowi 4.0 technologies, will further improve mortality rates. With regards to postsmolt, larger smolt is more robust, and the seawater phase can be reduced to one year given a smolt size of approx. 700 grams. This has the potential to significantly reduce mortality, as mortality mainly occurs in the seawater phase.

Mortality rates for Atlantic Salmon relatively stable over the past 30 years

Source: Kontali

* Loss rate = individuals / smolt release, where loss individuals = mortality, escape, culling and "other" (discards)

Sustainable production

5.3 Material sustainability efforts

Carbon footprint

The industry is constantly working to make the value chain more energy efficient and has set targets for reducing greenhouse gas (GHG) emissions. Sourcing of feed raw materials is the largest contributor of GHG emissions in salmon farming.

Plastic management

The presence of microplastic in the world's ocean is an emerging issue that fish farmers have started to focus on. Fish farmers are undertaking various initiatives to reduce plastic waste, such as improving waste management, engaging in beach clean-up events around the world, using improved packaging and monitoring the presence of microplastics and plastic-related contaminants in fish.

Escape prevention

Because escaped farm-raised salmon may have a negative impact on the environment due to interactions and interbreeding with wild populations, fish farmers have a target of zero escapes.

Sea lice

Effective sea lice management is important for fish welfare and to ensure sea lice on our farms do not negatively impact wild salmonids. Farmers work intensively to improve their approach to sea lice management and to minimise the number of adult female sea lice, especially during the period when wild salmon migrate to sea. A number of non-medicinal tools have been developed over the last years reducing significantly the use of medicines to manage sea lice.

Medicine use

Licensed medicines may have a negative environmental impact if used too frequently. Farmers use antimicrobial medicines only when fish health and welfare are at risk from bacterial infection and only when absolutely necessary. Antimicrobials are not used for growth promotion, prevention of infectious diseases or for control of dissemination.

Fish health and welfare

Caring about fish welfare is an ethical responsibility. The industry works every day to safeguard the health and welfare of fish through effective sea lice management, and to reduce medicine use by optimising fish survival and preventing disease. Operational welfare indicators are also monitored during production.

Biodiversity

The industry needs healthy oceans to drive sustainable salmon farming, and farmers must pay attention to the critical and highly sensitive environment they operate in. In all farming countries there are regulations in place to safeguard farming's impact on the seabed by monitoring the physical, chemical and biodiversity characteristics of the benthic environment.

Sustainable production

5.4 Sustainability of fish feed

Fish feed is a key component in ensuring the best possible fish health and performance. In any life cycle assessment (LCA)* of salmon farming, feed also makes the largest contribution to its environmental footprint. Important parameters for the carbon footprint arising from feed consumption are feed efficiency and feed ingredients.

Feed efficiency

The feed conversion ratio (FCR) describes the amount of feed used to produce a certain amount of salmon. Efficient feeding, that is, minimising feed waste, is important since the footprint of the feed release dominates the overall carbon footprint of the product. Improvements in feed formulations and in feed manufacture, combined with better on-farm feed management, can hugely reduce the quantity of feed (and thus the feed raw materials) used per kilogram of farmed aquatic food produced.

Feed ingredients

The current carbon footprint of farmed salmon shows that it is critical to change what the salmon is fed. Simply shifting between existing feed inputs, such as from marine to terrestrial inputs only leads to trade-offs between environmental impact categories.

In 1990 the average Norwegian salmon diet contained 65% fish meal and 24% fish oil. Marine ingredients have been reduced over time and in 2025 Mowi used 16% fish meal and 11% fish oils in its salmon feed. Production of fish meal and fish oils uses species from reduction fisheries and trimmings not suitable for human consumption.

Development of raw materials in salmon feed in Norway

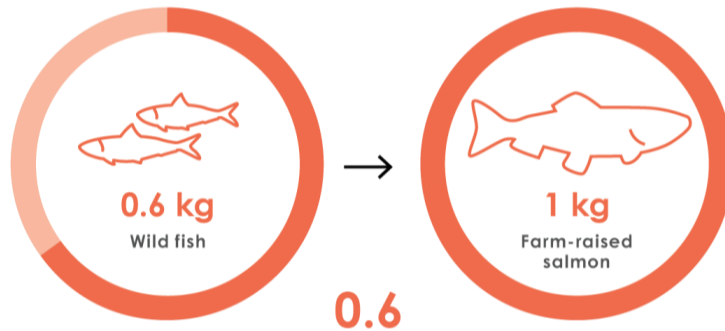

*Life Cycle Assessment (LCA) determines the environmental impacts of products, processes or services, through production, usage, and disposal

Source: SINTEF (2020) Greenhouse gas emissions of Norwegian seafood products in 2017, Ytrestøyl T., Aas T.S., Åsgård T. (2014) Resource utilization of Norwegian salmon farming in 2012 and 2013, NOFIMA, Mowi

Sustainable production

Recaptured Fish in- fish out (rFIFO)

Recaptured Fish in- fish out (rFIFO) express the number of kg of wild fish (excluding trimmings and the fish meal and oil produced from by-products originated from salmon processing) it takes to produce 1 kg of salmon. In 2025 Mowi used 0.6 kg of low consumer preference wild fish (like anchovy and sardine) to produce 1 kg of Atlantic salmon.

Substitution of marine raw materials has not been found to have any negative effect on growth, susceptibility to disease, or quality of the fish if the fish's own nutrient requirements are being covered.

Major reductions in carbon footprint could potentially come from exploring and developing feed ingredients that close the nutrient loop in the salmon industry (that increase overall resource efficiency) and developing ingredients from resources that are not utilised today. For example, products derived from insects, alcohol fermentation, CO₂ capture and forestry are currently being explored.

Traceability is important to make sure that no raw materials originate from illegal, unregulated and unreported (IUU) catches, or from fish species classified as endangered on the International Union for the Conservation of Nature (IUCN) red list. Sustainable sourcing of vegetable feed raw materials such as soy is ensured by purchasing from Proterra-certified (or equivalent) deforestation-free suppliers.

Sustainable production

5.5 Global sustainability initiatives

Achieving a sustainable future will require concerted action and new forms of partnership. One example of a key partnership is the Global Sustainable Seafood Initiative (GSSI). GSSI plays an important role in providing clarity on seafood certification. Third-party certifications can give consumers and stakeholders confidence that a product is sustainable. The Aquaculture Stewardship Council (ASC) and Global G.A.P. are examples of third-party certifications.

Global Sustainable Seafood Initiative (GSSI) aligns global efforts and resources to address seafood sustainability challenges. Governed by a Steering Board representing the full seafood value chain – companies, NGOs, governments and international organisations, including the FAO – GSSI promotes sector-wide collaboration to drive forward more sustainable seafood for everyone and maintains a benchmarking tool to assess sustainability standards.

The Aquaculture Stewardship Council (ASC) is an independent non-profit organisation with global influence. The ASC's primary role is to manage the global standards for responsible aquaculture. The ASC works with aquaculture producers, seafood processors, retail and foodservice companies, scientists, conservation groups and consumers.

Global G.A.P. is a recognised standard for farm production. Its goal is safe and sustainable agricultural production to benefit farmers, retailers and consumers throughout the world.

BAP (Best Aquaculture Practices) is a third-party certification programme that certifies every step of the production chain. BAP is part of GSA (Global Seafood Alliance), an international, nonprofit trade association dedicated to advancing responsible seafood practices through education, advocacy and third-party assurances.

Source: Mowi, gssi.org, asc-aqua.org, globalgap.org

Sustainable production

5.6 Transparency

Being transparent about environmental, social and product performance is key for building trust and correcting misinformation. The sustainability data is audited by third parties and reported according to global standards such as CDP (formerly the Carbon Disclosure Project) and FAIRR.

CDP is a not-for-profit charity that runs the global disclosure system for investors, companies, cities, states and regions to manage their environmental impacts. CDP supports thousands of companies, cities, states and regions to measure and manage risks and opportunities relating to climate change, water security and deforestation.

The FAIRR Initiative is a collaborative investor network that raises awareness of the material ESG risks and opportunities caused by intensive livestock production. FAIRR benchmarks global animal protein producers by assessing how they manage sustainability-related risks and opportunities, including biodiversity, pollution, antibiotics, labour standards and governance. In 2025, FAIRR introduced a dedicated seafood benchmark, recognising the sector's unique sustainability challenges and opportunities. Mowi has a strong track record in FAIRR's assessments, having been ranked the overall best-performing animal protein producer globally for six consecutive years (2019–2024), and topped FAIRR's dedicated seafood benchmark in 2025 by a clear margin.

The WBA **Seafood Stewardship Index (SSI)** measures the world's 30 most influential seafood companies and presents an overall ranking based on the results in four measurement areas: Governance and Strategy, Ecosystems, Traceability and Social Responsibility. These areas reflect where stakeholders expect corporate action, pinpointing where companies can have the most impact. Mowi ranked 4th in the 2023 benchmark and was the highest-ranked salmon farming company. This follows strong performances in previous editions of the index, where Mowi ranked 2nd overall in both 2021 and 2019.

6 Salmon Markets

Salmon Markets

6.1 Global trade flow of farmed Atlantic salmon

© 2026 Kontali. All rights reserved. Not to be reproduced, shared, or distributed without written consent from Kontali

The main markets for each production origin:

- Norway – Europe and Asia
- Chile – USA, South America and Asia
- Canada – USA
- Scotland – Domestic within UK, France

Each producing region has historically focused on developing the nearby markets. As salmon is primarily marketed as a fresh product, time and cost of transportation have driven this trend.

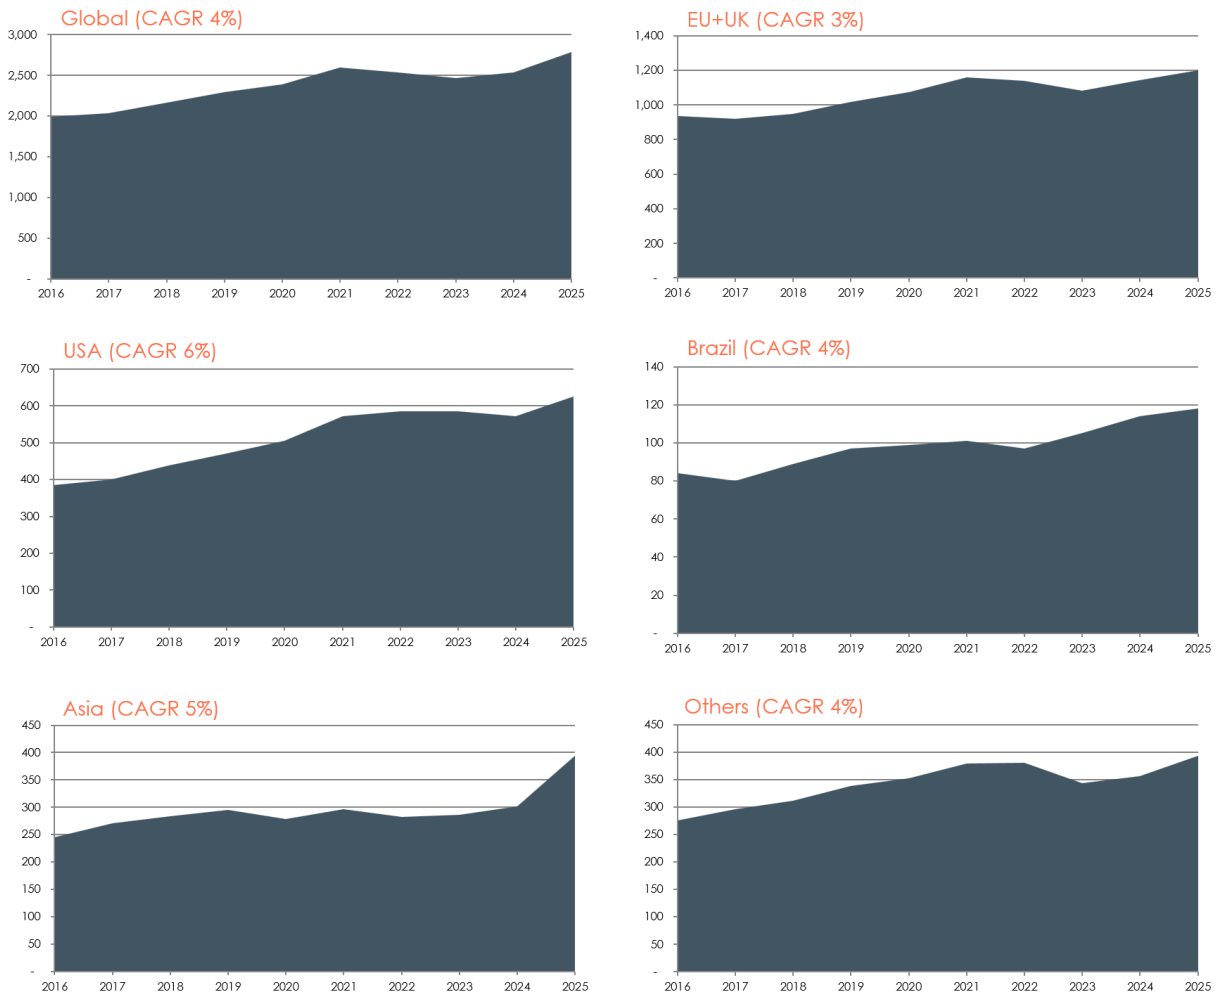

A relatively high price differential is therefore required to justify transatlantic trade as this incurs the cost of airfreight. Such trade varies from period to period and depends on arbitrage opportunities arising from short-term shortages and excess volumes from the various producing countries. As salmon is a global traded commodity market access without restrictions are important growth drivers. Any potential tariffs on imported salmon will eventually impact the end consumer prices, hence have an impact on trade flows over time.

The Asian market is generally shared as transportation costs are broadly similar from all producing regions. Distribution of frozen salmon is much more straightforward.

Note: Figures from 2025 and in thousand tonnes GWT. Not all markets are included.

Salmon Markets

6.2 Farmed Atlantic salmon by market

© 2026 Kontali. All rights reserved. Not to be reproduced, shared, or distributed without written consent from Kontali

EU+UK and USA are by far the largest markets for Atlantic salmon. On average consumption of Atlantic salmon has increased by 4% in all markets over the last 10 years due to constraints on supply. Although growth rates are relatively similar in the various markets the underlying demand in the US market has been the strongest. Underlying demand growth has also been strong in emerging markets such as Brazil and Asia (driven by China).

Note: Figures are in thousand tonnes GWT

Salmon Markets

6.3 Top 10 markets by size (2025E)

In the 10 largest markets by country, consumption per capita varies from 0.1 kg WFE to 3.9 kg WFE in France, which is high. In Norway, Sweden and Finland, consumption per capita is between 6–8 kg WFE. This means that there is significant growth potential among the largest markets.

Salmon Markets

6.4 Strong value growth of 8% CAGR last 10 years

© 2026 Kontali. All rights reserved. Not to be reproduced, shared, or distributed without written consent from Kontali

The value of salmon sold has increased by 104% from 2015 to 2025 (CAGR 8%), while volume has increased by 36% (CAGR 3%) over the same period. This highlights the strong underlying demand for salmon. 2022 stood out due to post-pandemic recovery, with global spending on salmon reaching EUR 20 billion, an all-time high level. In 2023 and 2024, market dynamics were normalising from the post-pandemic recovery experienced in earlier years. In 2025, unprecedented supply growth from strong biology put pressure on prices. However, underlying demand remained solid, with the market absorbing significantly higher volumes and supporting continued demand growth.

Hence, the price of salmon remained relatively stable in 2023 and 2024 despite limited global supply growth, before moving lower in 2025 due to increased supply. Demand, however, remained steady throughout the period. We expect the structural undersupply to persist in the coming years, with global supply growth projected at around 2% annually, while demand is expected to continue growing at approximately 8% p.a. This provides favourable supply and demand dynamics for the salmon industry.

Salmon Markets

6.5 Price neutral demand growth – approx. 10% the past 20 years

© 2026 Kontali. All rights reserved. Not to be reproduced, shared, or distributed without written consent from Kontali

Year	Global supply growth	Change in avg. price FCA Oslo (EUR)
2001	15%	-25%
2002	8%	-3%
2003	7%	-11%
2004	6%	7%
2005	5%	22%
2006	1%	23%
2007	10%	-21%
2008	5%	1%
2009	3%	12%
2010	-4%	34%
2011	12%	-17%
2012	22%	-10%
2013	2%	42%
2014	8%	-5%
2015	5%	-4%
2016	-4%	46%
2017	2%	-5%
2018	6%	-2%
2019	6%	-6%
2020	4%	-14%
2021	9%	14%
2022	-2%	40%
2023	-3%	0%
2024	3%	-5%
2025	10%	-15%

The historical correlation between change in global supply and average FCA Oslo price (EUR) is very strong. In the period 2001–2011, change in supply explained 84% of the change in price using linear regression. In 2012 and 2013 demand for salmon significantly overperformed. In the period 2014–2025, the correlation is lower due to, amongst other things, changing market dynamics and external shocks.

Price correlation across regional markets is generally strong for Atlantic salmon.

Growth in global supply of Atlantic salmon was 213% in the period 2001–2025 (CAGR 5%), varying between -4% and 22% annually. Variation in growth rates has been the main determinant for the variation in prices. However, in 2020, demand was impacted by Covid-19 restrictions which reduced foodservice activity. Demand partially recovered in 2021 as the pandemic waned and market conditions strengthened, and this positive

Source: Kontali Analyse

Salmon Markets

trend continued into 2022 as demand experienced a notable recovery as the pandemic's effects diminished further and market conditions improved. In 2023, global demand saw a slight dip, with volume decreasing by 3%. Nevertheless, spot prices managed to stabilise at the elevated levels observed in 2022. In 2024, global harvest volumes increased by 3%, although this was accompanied by slightly lower spot prices compared to the previous year. In 2025, global harvest volumes increased significantly by 10%, driven by strong biology in all salmon producing regions, while spot prices declined by 15% as the market absorbed the substantial increase in supply.

Since 2014, prices have ranged between EUR 7.87 per kg (2022) and EUR 4.52 per kg (2015).

Salmon Markets

6.6 Historic price development

As salmon is perishable and marketed fresh, all production in one period must be consumed in the same period. In the short term, the production level is difficult and expensive to adjust as the planning/production cycle is three years long. Therefore, the supplied quantity is very inelastic in the short term, while demand shifts according to the season. This is the main reason for the price volatility in the market.

Factors affecting market price for Atlantic salmon are:

- Supply (absolute and seasonal variations)
- Demand (absolute and seasonal variations)
- Globalisation of the market (arbitrage opportunities between regional markets)
- Presence of sales contracts reducing quantity available for the spot market
- Flexibility of market channels
- Quality
- Disease outbreaks
- Food scares

Comparing FCA Oslo, FOB Miami and FOB Seattle, there is a clear indication of a global market as prices correlate to a high degree.

As in most commodity industries, producers of Atlantic salmon experience high volatility in the price achieved for the product. The average price (GWT based) for Norwegian whole salmon since 2016 has been about EUR 6.7/kg, for Chilean salmon fillet (3–4 lb) D-trim fillet USD 5.5/lb (USD 7.8/kg GWT equivalent), and for Canadian salmon (10–12 lb) USD 3.5/lb (USD 7.8/kg). The pricing of Scottish and Faroese salmon is linked to the price of Norwegian salmon. The price of Scottish salmon normally has a premium to Norwegian salmon. Faroese salmon used to trade at a small discount to Norwegian salmon. However, due to geopolitical events in the last decade, salmon from the Faroes now trades at a premium over Norwegian salmon in selected markets.

Note: The black line represents Norwegian yearly avg. prices.

Source: Kontali Analyse, Nasdaq, Urner Barry

Salmon Markets

6.7 Different sizes – different prices (Norway)

Relative Prices

© 2026 Kontali. All rights reserved. Not to be reproduced, shared, or distributed without written consent from Kontali

The main reason for differences in size is the biological production process in which individual fish grow at different rates. A farm holding fish of harvestable size will show a normally distributed size distribution. This results in most fish being harvested at 3–6 kg GWT, with fewer fish harvested at both smaller and larger sizes.

The processing industry in Europe mainly uses 3–6 kg GWT but niche markets exist for smaller and larger fish. As these markets are minor compared to the main market, they are easily disrupted if quantities become too large. Generally, small fish are discounted, and large fish are sold at premium as shown in the graph above.

Size distribution

The graph to the left shows Norwegian harvest distribution for 2025, with the harvest size of 4–5 kg (GWT) being the most frequent. In addition to catering for production process and market requirement, another driver behind this size fluctuation is that farmers want to balance out market risk and biological

risk. Drivers behind smaller harvest size can be disease, early harvest when there is a need for cash flow, or early harvest to realise ongoing capacity. Larger fish (6–7 kg+) may be a result of economies of scale/lower production costs, production for niche markets or other market requirements.

Top 5 companies by harvest volume 2025

Mowi Group represents the largest total production, harvesting one fifth of the salmon produced in Norway and other Europe and approx. one third of total production in both the UK and North America.

In Norway and Chile there are several other producers of significant size. In Chile, several of the companies also produce other salmonids, such as Coho and large trout.

Harvest volume - Atlantic salmon 2025

Industry Structure

7.2 Number of companies in producing countries

© 2026 Kontali. All rights reserved. Not to be reproduced, shared, or distributed without written consent from Kontali

The graph shows the number of companies producing 80% of the farmed salmon and trout in each major producing country.

Historically, the salmon industry consisted of a larger number of smaller firms. As illustrated above, this was the case in Norway, and to some extent in Scotland and Chile.

During the last decades the salmon farming industry has been through a period of consolidation in all regions, and this is expected to continue.

There are approx. 100 companies owning commercial licenses for salmon and trout in Norway, however some of these are controlled by other companies. The total supply is produced by around 90 companies (directly or through subsidiaries).

There are approximately 1,360 commercial licenses for on-growing of Atlantic salmon, trout and coho in Chile, whilst only 390 licenses are in operation. The 10 largest firms account for 90% of total licenses.

Note: See appendix for some historical acquisitions and divestments
Source: Kontali Analyse

8 Salmon Production and Cost Structure

Salmon Production and Cost Structure

8.1 Establishing a salmon farm

The salmon farming production cycle is about 3 years. During the first year of production eggs are fertilised and fish are grown to approximately 100–250 grams in a controlled freshwater environment. In recent years, the industry has invested in freshwater facilities that can grow the smolt larger, up to 1,000 grams, thus shortening the time at sea.

The fish are then transported to seawater cages where they are grown to around 4–5 kg over a period of 12–24 months. The growth of the fish is heavily dependent on seawater temperatures, which vary by time of year and across regions.

When they reach harvestable size, the fish are transported to processing plants, where they are slaughtered and gutted. Most salmon is then sold gutted on ice in boxes (GWT).

Salmon Production and Cost Structure

8.2 The Atlantic salmon life/production cycle

The freshwater production cycle until smoltification takes approximately 10–18 months, while the seawater production cycle lasts around 10–24 months, resulting in a total production cycle of approximately three years, including fallowing. Post-smolt will normally have a longer production cycle in freshwater and a shorter production cycle in seawater, depending on smolt size. In Chile, the production cycle is slightly shorter, as seawater temperatures are more favourable and subject to fewer fluctuations.

In autumn, broodstock are stripped for eggs, and ova inlay takes place between September and April. The producer can speed up the growth of the juveniles with light manipulation which accelerates the smoltification process by up to 6 months.

Spring and autumn are the two main periods to release smolt in Norway. However, there are smolt being released in all twelve months of the year.

Note: See appendix for more information on the Atlantic salmon production cycle
Source: Mowi

Salmon Production and Cost Structure

Harvesting is spread throughout the year, although most harvesting takes place during the second half of the year, when growth rates are at their highest. During summer, harvesting shifts to a new generation, resulting in a wider size distribution among harvested salmon. Consequently, the variation in harvest weights is greater at this time of year than during the rest of the year.

After a site is harvested, the location is fallowed for between 2 and 6 months before the next generation is put to sea at the same location. Smolts may be released in the same location with a two-year cycle.

Salmon Production and Cost Structure

8.3 Influence of seawater temperature

Seawater temperatures vary considerably throughout the year in all production regions. While the production countries in the northern hemisphere see low temperatures at the beginning of the year and high temperatures in autumn varying by as much as 15°C, the temperature in Chile is more stable varying between 10°C and 14°C. Chile and Ireland have the highest average temperatures of 11–12°C, while the four other regions average around 9°C, except for Iceland, which has the lowest average temperature at 6°C.

As the salmon is a cold-blooded animal (ectotherm), water temperature plays an important role in its growth rate. The optimal temperature range for Atlantic salmon is 8–14°C, but they thrive well from 4–18°C. Temperature is one of the most important natural competitive advantages that Chile has compared to the other production regions as production time there has historically been shorter by a few months.

With high seawater temperatures the risk of disease increases, and with temperatures below 0°C, mass mortality becomes more likely, both of which cause the growth rate to fall.

Salmon Production and Cost Structure

8.4 Production inputs

Eggs

There are several suppliers of eggs to the industry. AquaGen, Benchmark Genetics and Rauma Stamfisk are some of the most significant by quantity. In addition to these suppliers, Mowi produces its own eggs based on the Mowi strain.

Egg suppliers can tailor their deliveries through use of broodstock with favourable genetics for different traits desired by customers, and several suppliers are able to produce eggs throughout the whole year. The market for salmon eggs is international, although this can be subject to import/export restrictions imposed by different countries.

Smolt

The majority of smolt are produced “in-house” by vertically integrated salmon farmers. This production is generally for a company’s own use, although a proportion may also be sold to third parties. A smolt is produced over a period of 8–12 months from first feeding to a mature smolt weighing 100–250 grams. Post-smolt production (250–1,000 grams) has become more common in recent years, accounting for 24% of the Norwegian smolt release in 2024 in terms of individuals. The idea behind larger smolt is to shorten production time at sea, thus reducing exposure to sea lice and fish diseases, and improving fish welfare.

Salmon Production and Cost Structure

Labour

According to the Directorate of Fisheries, the Norwegian aquaculture industry directly employed 11,340 people in 2025, up 6.5% from 2024. A MENON publication from 2022 estimated total direct and indirect employment within aquaculture at 19,000 people. Including processing and supplier industries, total employment amounted to 62,500 people.

According to Salmon Scotland, more than 2,500 people are directly employed in Scottish salmon farming, while the industry supports over 10,000 additional jobs across the country.

According to the Canadian Aquaculture Industry Alliance (CAIA), the Canadian aquaculture sector employed around 18,000 full-time workers in 2024, including more than 13,000 jobs within salmon farming and processing.

According to SalmonChile, the Chilean salmon industry supported around 86,000 direct and indirect jobs in 2025, including approximately 45,000 direct employees within salmon farming companies.

As of 31 December 2025, Mowi Group employed 14,195 people worldwide across 26 countries (including third-party employees).

Electricity

Electricity is mainly used in the earliest and last stages in the salmon's life cycle. To produce a good quality smolt, production normally takes place in tanks on land where the water temperature is regulated and water may be recirculated, which requires energy (accounting for approx. 7–8% of smolt cost in Norway). The cost of energy consumption will depend on the price of electricity and the temperature. A cold winter will demand more electricity to heat the water used in the smolt facility. The size of the smolt will also influence electricity consumption as a larger smolt has a longer production cycle in the smolt facility. More energy is consumed when the salmon is processed. However, this depends on the level of automation (3–4% of harvest cost in Norway).

Source: Mowi, Kontali Analyse, Directorate of Fisheries, MENON, Salmon Scotland, CAIA, SalmonChile

Salmon Production and Cost Structure

8.5 Cost component – disease and mortality

Production costs per kg decline with increasing harvest weight. If fish are harvested below the optimal weight, for example due to disease, production costs per kg will be higher.

During the production cycle, some mortality will occur. Under normal circumstances, the highest mortality rate will be observed during the first 1–2 months after the smolt is put into seawater, while subsequent stages of the production cycle normally have a lower mortality rate.

Elevated mortality in later months of the cycle is normally related to outbreaks of disease, treatment for sea lice or predator attacks.

There is no strict standard for how to account for mortality, and there is no unified industry standard. Three alternative approaches are:

- Charge all mortality to expense when it is observed
- Capitalise all mortality (letting the surviving individuals carry the cost of dead individuals in the balance sheet when harvested)
- Only charge exceptional mortality to expense (mortality, which is higher than what is expected under normal circumstances)

It is not possible to perform biological production without any mortality. By capitalising the mortality cost, the cost of harvested fish will reflect the total cost for the biomass that can be harvested from one production cycle.

Salmon Production and Cost Structure

8.6 Accounting principles for biological assets

Biological assets are measured at fair value less cost to sell, unless the fair value cannot be measured reliably.

Effective markets for the sale of live fish do not exist, meaning the valuation of live fish is based on an estimated fair value in a hypothetical market. Fair value is estimated using a calculation model, where cash inflows are derived from estimated volumes multiplied by estimated prices. Fish ready for harvest (4 kg GWT, corresponding to 4.8 kg LW) is valued at expected sales prices less estimated harvest, transport and other related costs to arrive at back-to-farm prices. For fish not ready for harvest (i.e. below 4 kg GWT), the model implies an interpolation methodology based on two known data points: *i)* the value of the fish at sea transfer and *ii)* the estimated value at harvest size. The valuation also reflects expected quality grading and size distribution.

Broodstock and smolt are measured at cost less impairment losses, as fair value cannot be measured reliably.

The change in estimated fair value is recognised in profit or loss on a continuous basis and is classified separately (not included in the cost of the harvested biomass). On harvesting, the fair value adjustment is reversed on the same line.

Operational EBIT

Operational EBIT and other operational results are reported based on the realised costs of harvested volume and do not include fair value adjustments on biomass.

Salmon Production and Cost Structure

8.7 Economics of salmon farming

The salmon farming industry is capital-intensive and volatile. This is a result of a long production cycle, a fragmented industry, market conditions and a biological production process which is affected by many external factors.

Over time, production costs have declined and productivity has improved due to new technology and more efficient farming techniques. In recent years, costs have trended upwards due to several factors, including higher feed costs, increased biological challenges and more stringent regulatory requirements.

Reported revenues: Revenues are a gross figure; they can include invoiced freight from reference place (e.g. FCA Oslo) to customer, and have discounts, commissions and credits deducted. Reported revenues can also include revenues from trading activity, sales of by-products, insurance compensation, gain/loss on sale of assets etc.

Price: Reported prices are normally stated in the terms of a specific reference price e.g. the Nasdaq price for Norway (FCA Oslo) and UB price for Chile (FOB Miami). Reference prices do not reflect freight, and other sales reducing items mentioned above. Reference prices are for one specific product (Nasdaq price = sales price per kg head on gutted fish packed fresh in a standard box). Sales of other products (frozen products, fresh fillets and portions) will cause deviation in the achieved prices vs. reference price. Reference prices are for superior quality fish, while achieved prices are for a mix of qualities, including downgrades. Reference prices are spot prices, while most companies will have a mix of spot and contract sales in their portfolio.

Quantity: Reported quantity can take many forms. Quantity harvested = Fish harvested in a specific period in a standardised term; e.g. Gutted Weight Equivalent (GWT), which is the same weight measure as Head-on-Gutted (HOG), or Whole Fish Equivalent (WFE), the difference being gutting loss. Quantity sold can be reported using different weight scales:

- Kg sold in product weight.
- Kg sold converted to standard weight unit (GWT or WFE).
- Quantity sold could also include traded quantity.

Salmon Production and Cost Structure

8.8 Cost structure industry Norway 2016–2025 (CAGR 3%)

© 2026 Kontali. All rights reserved. Not to be reproduced, shared, or distributed without written consent from Kontali

Feed: As in all animal production, feed accounts for the largest share of total costs. Cost variations between countries are mainly driven by differences in feed inputs, logistics and feed conversion ratios. In 2022, feed costs increased significantly due to higher feed prices and inflationary pressures.

Smolt: Atlantic salmon smolt is largely produced at land-based hatcheries, either in flow-through or RAS systems. Cost per kilo is increasing as farmers increase the smolt size in hatcheries prior to sea transfer. The higher cost is expected to be offset by shorter time spent at sea and reduced lice treatment.

Labour cost: While salmon production is a capital-intensive industry, labour costs account for only a minor share of total costs. Labour costs increased during the period 2014–2017, partly due to increased employment related to lice challenges, but have remained relatively stable in recent years.

Harvest / Packing / Well boat: Costs related to transportation of live fish, slaughtering, processing and packing are heavily dependent on harvest volumes, logistics and automation.

Depreciation: The industry is investing heavily in new technology and automation, as well as equipment used for lice treatment, resulting in higher depreciation costs.

Misc. operating costs: Other costs include direct and indirect costs, administration, insurance and biological costs (excluding mortality).

9 Feed Production

Feed Production

9.1 Overview of feed market

Global production of manufactured feed (2025)

© 2026 Kontali. All rights reserved. Not to be reproduced, shared, or distributed without written consent from Kontali

Global production of manufactured feed was around 1,440 million tonnes in 2025. The majority was used for land-dwelling animals, where 88% was used in the farming of poultry, pig and ruminants. Only 4%, or 56 million tonnes, of global production of manufactured feed was used in aquatic farming.

Global production of aquatic feed (2025)

© 2026 Kontali. All rights reserved. Not to be reproduced, shared, or distributed without written consent from Kontali

Most aquatic feed produced globally is used for carp as this is the predominant farmed fish species. Feed for salmonids only accounts for 10% of the total production of aquatic feed.

Feed Production

Global production of feed to salmonids (2025)

© 2026 Kontali. All rights reserved. Not to be reproduced, shared, or distributed without written consent from Kontali

Atlantic salmon is the most farmed species of salmonids and is therefore the largest consumer of salmonid feed..

Development in Salmonid feed markets

© 2026 Kontali. All rights reserved. Not to be reproduced, shared, or distributed without written consent from Kontali

Most of the feed used in farming of salmonids is produced close to where it is farmed. Norway used 45% of the global feed directed towards the salmonid segment in 2025 and Chile used 29%.

Feed Production

9.2 Relative feeding

Relative feeding - seasonal profile (average 2021-2025)

© 2026 Kontali. All rights reserved. Not to be reproduced, shared, or distributed without written consent from Kontali

The production of feed around the world varies as there are large deviations in sea temperature. Norway has the greatest seasonality in production. The low season is from February to April, and the high season is from July to October, with the mid-season in between. Production in the low season can be as low as only 30% of the high season's production. Over a year, Chile has the highest relative feeding, measured by feed sold or fed during a month relative to the incoming biomass. Feed is considered a perishable product with limited opportunities to store.

*Relative feeding: Feed sold or fed during a month / Biomass per primo in month
Source: Kontali Analyse

Feed Production

9.3 Salmon feed producers

During the last decade, the salmonid feed industry has become increasingly consolidated. Together with Mowi, three producers now control the majority of salmon feed output; Skretting (subsidiary of Nutreco which has been acquired by SHV, EWOS (Cargill), and BioMar (subsidiary of Schouw). These companies all operate globally.

In mid-2014, Mowi began production of feed from its first new feed plant. In 2019, Mowi completed its second feed plant located in Kyleakin, Scotland. Mowi has a total production capacity of 750,000 tonnes. In 2025 Mowi produced 587,818 tonnes compared with total global salmonid feed production of around 5.5 million tonnes.

The major cost elements when producing salmonid feed are the raw materials required and production costs.

The feed producers have historically operated on cost-plus contracts, leaving the exposure to raw material prices with the aquaculture companies.

Feed Production

9.4 Salmon feed ingredients

Growth intervals	0.1 - 0.2 kg	0.2 - 1 kg	1 - 2 kg	2 - 3 kg	3 - 4 kg	4 - 5 kg
Feed consumption (Norway)	0.08 kg	0.75 kg	1.00 kg	1.05 kg	1.10 kg	1.20 kg
Time, months	2	4	4	3	2	2

Atlantic salmon feed should provide proteins, energy and essential nutrients to ensure high muscle growth, energy metabolism and good health. Historically, the two most important ingredients in fish feed have been fish meal and fish oil. The use of these two marine raw materials in feed production has been reduced in favour of ingredients such as soy, sunflower, wheat, corn, beans, peas, poultry by-products (in Chile and Canada) and rapeseed oil. This substitution is mainly due to heavy constraints on the availability of fish meal and fish oil.

Atlantic salmon have specific nutrient requirements for amino acids, fatty acids, vitamins, minerals and other lipid- and water-soluble components. These essential nutrients can in principle be provided by the range of different raw materials listed above. Fish meal and other raw materials of animal origin have a more complete amino acid profile and generally contain more protein than plant-based protein sources. As long as fish receive the amino acids they require, they will grow normally and remain healthy, and the composition of their muscle protein will be the same regardless of the protein source in the feed. Consequently, feeding salmon with non-marine protein sources results in a net production of marine fish protein.

During the industry's early phases, salmon feed was moist (high water content) with high levels of marine protein (60%) and low levels of fat/oil (10%). In the 1990s, feed typically consisted of 45% protein, made up mostly of marine protein. Today, the marine protein level is lower due to cost optimisation and the availability of fish meal. However, the most interesting development has been the increasingly higher inclusion of fat. This has been made possible through technological development and extruded feeds.

Feed Production

Feed and feeding strategies aim to grow a healthy fish fast at the lowest possible cost. Standard feeds are designed to give the lowest possible production cost rather than maximised growth. Premium diets are formulated to give amongst other things better growth rate and higher survival.

Feeding control systems are used at all farms to control and optimise feeding. Feeding is monitored for each net pen to ensure that fish are fed to maximise growth (measured by the Relative Growth Index (RGI)). At the same time systems ensure that feeding is stopped immediately when the maximum feed intake has been provided to prevent feed waste. The fastest growing fish typically also have the best (i.e. lowest) feed conversion ratio (FCR).

Feed Production

9.5 Feed raw material market

Fish oil: In general, fish oil prices are more volatile than vegetable sources mainly due to volatile supply as result of the quota systems for fisheries. The average price of fish oil was about USD 3,900 per tonne in 2022 mainly due to low availability of raw material. Throughout 2023, the price of fish oil continued its ascent following the cancellation of Peru's first anchovy season. The second season saw notably diminished oil yields, resulting in a mere 6,000 tonnes fish oil produced, which further increased prices. However, throughout 2024 and 2025 the anchovy fishing seasons in Peru have seen improved yields which has translated into higher production of fish oil, and prices have declined in the last years. However, more recently we have seen a new spike in fish oil prices on supply constraints due to reduced harvest volumes of

Fish meal: Fish meal has seen stable price development over the past ten years. Although prices have been stable based on a yearly average, there are large variations within the years. The market for fishmeal is small compared with that for vegetable proteins.

Rapeseed oil: Up until 2011, rapeseed oil price development was correlated with fish oil but from 2011 to 2015 prices fell each year and it traded significantly below fish oil. The price has been hovering around USD 800–900 per tonne in recent years, but in 2021 and 2022 the price increased. However, in 2023, the price moderated back to historical levels.

Soy meal: Soy and corn have traditionally been important vegetable protein sources in fish feed. Prices have been under pressure in recent years due to increased supply, particularly from expanded production in Brazil. However, in 2021 and 2022, soy prices increased in line with other soft commodity prices.

Wheat: Prices for wheat have remained stable over the years with generally good production and balanced supply/demand. In 2022 wheat prices increased in line with other soft commodity prices, however, in 2023, prices softened and traded below historical levels.

Source: Holtermann

10 Financial Considerations

Financial Considerations

10.1 Working capital

The long production cycle of salmon requires significant working capital in the form of biomass.

Working capital investments are required for organic growth, as a larger “pipeline” of fish is needed to facilitate larger harvest volumes. On average, a net working capital investment of approximately EUR 3.5/kg is required, split between the year of harvest and the year immediately preceding harvest, in order to obtain an increase in harvest volume of 1 kg. The working capital requirement has increased over time and fluctuates with variations in currency exchange rates and production costs. Working capital tie-up increased through 2022, driven by inflationary pressure on input costs, and continued to rise through 2023 and 2024. Through 2025 and into early 2026, this development has slowed, with signs of stabilization.

Net working capital varies during the year. Growth of salmon is heavily impacted by changing seawater temperatures. Salmon grows at a higher pace during summer/autumn and more slowly during winter/spring when the water is colder. As the harvest pattern is relatively constant during the year, this leads to large seasonal variations in net working capital. For a global operator, net working capital normally peaks around year-end and bottoms out around mid-summer.

Source: Mowi

Financial Considerations

Cost of building biomass

For illustration purposes, the farming process has been divided into three stages of 12 months each. The first 12-month period covers production from egg to finished smolt, followed by 24 months of on-growing at sea. Harvest takes place immediately after the on-growing phase ends (illustrated as "Month 37"). In a steady-state operation, there will always be three different generations at different stages of their life cycle. Capital expenditure is assumed to equal depreciation for illustration purposes. Working capital effects are shown on a net basis, excluding the effects of accounts receivable and accounts payable.

By the point of harvest there have been up to 36 months of costs to produce the fish, comprising the cost of producing the smolt two years ago, further costs incurred to grow the fish in seawater, and some costs related to harvest ("Month 37"). Sales price covers these costs and provides a profit margin (represented by the orange rectangle).

Cash cost for the period in which the fish are harvested is not large compared to sales income, creating a high net cash flow. If production going forward (next generations) follows the same pattern, most of the cash flow will be reinvested into salmon at various growth stages. If the company wishes to grow its future output, the following generations need to be larger requiring even more of the cash flow to be reinvested in working capital.

This is a rolling process and requires substantial amounts of working capital to be tied up, both when in a steady state and especially when increasing production..

Source: Mowi

Financial Considerations

The illustration above shows how capital requirements develop when production/biomass is being built “from scratch”. In phase 1, there is only one generation (G) of fish produced and the capital requirement is the production cost of the fish. In phase 2, the next generation is also put into production, while the on-growing of G1 continues, rapidly increasing the capital invested. In phase 3, G1 has reached its last stage, G2 is in its on-growing phase and G3 has begun to increase its cost base. 39F1

At the end of phase 3, the harvest starts for G1, reducing the capital tied up, while the next generations continue to build up their cost base. If each generation is equally large and all other factors remain unchanged, the capital requirement will peak at the end of phase 3. With growing production, the capital requirement will continue to increase after phase 3 if the next generation is larger than the previous one (otherwise, the capital base is reduced). This illustrates that salmon farming is a capital-intensive industry.

To equip a grow-out facility you need cages (steel or plastic), moorings, nets, cameras, feed barge/automats and workboats.

Financial Considerations

10.2 Capital return analysis

Investments and payback time (Norway) – assumptions

- Normal site consisting of 4 licenses
- Equipment investment: MEUR 6.8 - 8.5
- Number of licenses: 4
- License cost (second hand market) MEUR: 72 (EURm ~18 per license)
- Output per generation: ~4,900 tonnes GWT
- Number of smolt released: 1,300,000

- Smolt cost per unit: EUR 2.4
- Feed price per kg: EUR 1.6 (LW)
- Economic feed conversion ratio (FCR): 1.3 (to Live Weight)
- Conversion rate from Live Weight to GWT: 0.84
- Harvest and processing incl. well boat cost per kg (GWT): EUR 0.40

- Average harvest weight (GWT): 4.4kg
- Survival rate in sea: 86%

- Sales price: EUR 7.5/kg

- Corporate tax rate: 22%
- Resource rent tax: 25% (seawater phase only), assumed 10% effective increase in tax (assumed 40% of value chain subject to resource rent tax)
- Farming contributions only (no earnings contributions from rest of value chain)

To increase capacity there are many regulations to fulfil. In this model we focus on a new company entering the industry and we have used only one site, for simplicity's sake. Most companies use several sites concurrently, which enables economies of scale and makes the production more flexible and often less costly.

In this model smolts are bought externally, also in the interests of simplicity. Smolts are usually less costly to produce internally, but this depends on production quantity.

Fish performance is affected by numerous factors including feeding regime, seawater temperature, disease, oxygen level in water, smolt quality, etc.

The average price from the previous years' auctions is used as a basis for license cost.

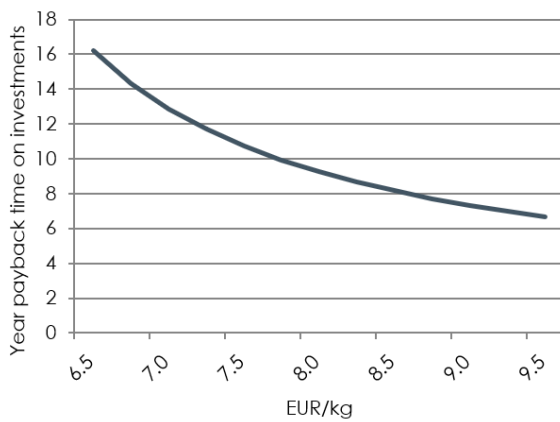

Sales price reflects the average sales price from Norway in the period 2022–2026 YTD.

Source: Mowi, Kontali Analyse

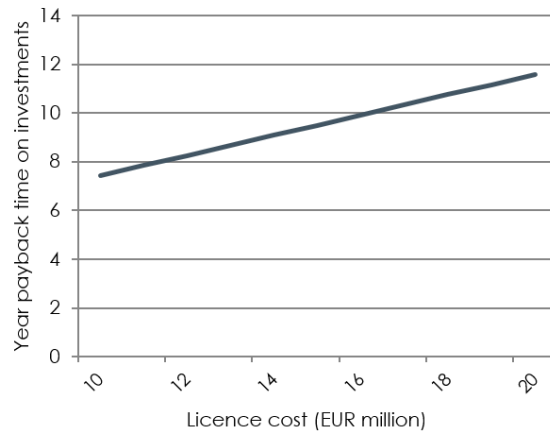

Financial Considerations

Results

Payback time varying sales price

Payback time varying licence cost

Due to high entry barriers in terms of capital needs, and falling production costs with increasing quantity, new entrants into the salmon farming industry will experience higher average production costs. During the production of each generation the working capital needed at this farm would peak at around MEUR 13.

With a sales price of EUR 7.5/kg the payback time for the original investments would be around 12 years. This result is very sensitive to sales price, license cost and economic feed conversion ratio (FCR). Note that the earnings contributions are from the farming operations only, and do not include earnings contributions from the rest of other parts of the value chain.

The sales price of EUR 7.5/kg is based on the average price in Norway from 2022–2026 YTD.

Financial Considerations

10.3 Currency overview

Norwegian exposure vs foreign currency – average last 5 years⁽¹⁾.

Exporters deal in the traded currency, while the customer has an exposure to both traded and local currencies. For example, a French processor may trade salmon in NOK but sell its products in the local currency (EUR).

Most Norwegian producers are exposed to currency fluctuations as most of the salmon they produce is exported. Most of the salmon is exported to countries within the EU and is traded in EUR. The second largest traded currency is USD. Some players in countries in Eastern Europe, the Middle East and some Asian countries prefer to trade salmon in USD rather than in local currency.

The price of salmon quoted in traded currency will compete with other imported goods, while the price of salmon quoted in local currency will compete with the price to consumers of domestically produced products.

There is a currency risk involved in operating in different currencies, and therefore many of the largest industry players hedge currencies often with back-to-back contracts. The currency risk arising from salmon sales denominated in the traded currency is usually absorbed by the exporter, while the currency risk in local currency is absorbed by the customer.

Note: (1) The table shows exposure against local currency weighted against total export volumes

Source: Kontali Analyse

Financial Considerations

Exposure against local currency – 2025⁽¹⁾

Europe is the largest market for Norwegian produced salmon, so EUR is the predominant currency for Norwegian salmon producers.

Key markets for Chilean produced salmon are the USA and Brazil, so exposure to USD and BRL (Brazilian real) in local currency terms is followed closely.

Feed production: Currency exposure

The raw materials required to produce feed are as a rule of thumb quoted in USD (approx. 70%) and EUR (approx. 30%), based on long term average exchange rates. Raw materials generally account for 85% of the cost of producing feed. The remaining costs, including margin for the feed producer, are quoted in local currency.

Secondary Processing: Currency exposure

The biggest market for value-added products is Europe, and therefore most currency flows are EUR-denominated on both the revenue and cost sides. In the US and Asian processing markets, revenues are primarily denominated in USD and EUR, while costs are denominated in USD, EUR and local currencies.

Note (1): The table shows exposure against local currency weighted against total export volumes

Financial Considerations

10.4 Price, cost and EBIT development in Norway

Norwegian profitability over time

© 2026 Kontali. All rights reserved. Not to be reproduced, shared, or distributed without written consent from Kontali

Atlantic salmon is seen as a healthy, resource-efficient, and climate friendly product. On the back of a growing global middle class, an aging population, a global trend towards healthy living, and a focus on carbon footprint, demand has been estimated to grow by 8% per annum the last decade. Product innovation, category management, long-term supply contracts, effective logistics and transportation have stimulated strong demand growth for salmon.

An essential characteristic of the salmon market is that supply is limited due to regulations and biological conditions. However, over the years there have been several supply shocks. In Chile, the ISA virus outbreak which lasted until 2010 and the algae bloom in 2016 caused negative supply shocks which in isolation caused positive price movements. In 2020, a temporary demand shock caused by Covid-19 restrictions, which partly closed the foodservice sector, resulted in negative price development. In 2021, the pandemic waned and markets partially recovered. In 2022 prices increased further on foodservice demand recovery and a slight global supply contraction. In 2023 and 2024, prices stabilised compared to the high base in 2022, followed by a year of lower prices in 2025 due to higher-than-expected supply growth.

Over the last ten years, costs have trended upwards due to several factors including rising feed costs, biological costs and more stringent regulatory compliance procedures. The average EBIT per kg for the Norwegian industry has been positive with the exception of a few shorter periods. In the last 10 years it has been EUR 1.7 per kg in nominal terms.

Source: Kontali Analyse, Norges Bank

Financial Considerations

10.5 Effects of geographical diversification

The illustration above depicts Mowi's performance across different countries over the last 5 years. In all regions, the biological risk is high, and this impacts cost significantly from period to period. The variance in EBIT per kg is high, however, the geographic specific risk can be diversified with production across regions.

Source: Mowi

Financial Considerations

10.6 Return on Capital Employed

Salmon farming is a capital-intensive industry with investments in licenses, freshwater facilities, seawater equipment, processing capacity and supporting infrastructure, including a long production cycle with an associated biomass/working capital tie-up. As described in the previous sections, organic growth requires a larger pipeline of fish and therefore increased working capital, while new capacity may also require significant investments in licenses and fixed assets. Return on capital employed is therefore a key measure of economic performance in salmon farming, as it captures both operational profitability and the capital required to generate that profitability.

EBIT per kg is a useful measure of operational performance, but it does not capture the full economic return of the business. ROCE reflects the earnings generated relative to the capital employed, and is therefore affected by both profitability, capital intensity and how efficient the asset base is utilised. This means that higher EBIT per kg improves returns, but the return will also depend on how efficient the capital base is used to generate revenues. Asset turnover is therefore an important part of the ROCE equation. Investments such as larger smolt and post-smolt may increase the capital base, but can also reduce production time at sea, improve license utilisation and increase harvest volumes relative to capital employed. In such cases, higher invested capital can contribute to higher ROCE provided asset turnover and/or margins improve sufficiently

Over time, the salmon farming industry has increased investments in technology, larger smolt, sea lice mitigation, fish health, automation, processing capacity and more robust farming infrastructure. These investments are important to improve biological performance, fish welfare, operational control and long-term growth potential. However, they also increase the capital base of the industry. Combined with higher working capital requirements and higher license values (for new capacity) in certain regions, this has contributed to pressure on industry ROCE over time. When comparing ROCE across companies, differences in value chain exposure should also be taken into account, as companies with integrated feed, processing and sales activities will typically have a different capital base than companies with a more focused farming exposure.

Industry ROCE

Source: Mowi

Financial Considerations

Geographical differences in return on capital employed

Biological risk is high in all farming regions, and this impacts volumes, cost and EBIT per kg from period to period. Production across several regions can therefore reduce exposure to region-specific biological and operational events. However, geographical diversification is also relevant from a capital allocation perspective, particularly when assessing investment decisions across farming regions.

The return on additional volume growth is determined by both expected operational efficiency (volumes), EBIT per kg and the capital required to generate an additional kg. Capital employed per kg varies between farming regions due to differences in license regimes, fixed asset requirements, production cycles and working capital tied up in biomass. In regions where new growth requires investments in licenses, infrastructure and biomass, the capital employed per kg can be significant. In regions where operators have available capacity or unused licenses, incremental growth may require lower capital commitment.

As a result, new volume growth in a region with a lighter asset model can generate higher returns on capital despite lower EBIT per kg. Geographical diversification should therefore be assessed through both operational profitability and capital intensity, as the combination determines long-term value creation.

As an illustrative example, the return on new production volumes can differ materially between regions. In Chile, unused license capacity can reduce the license component of the investments, resulting in higher ROCE despite lower EBIT per kg:

ROCE	Norway	Chile
Capital Employed/kg:		
License	14.2	N/A
Fixed Assets	4.0	3.0
Inventory	3.0	3.0
	<u>21.2</u>	<u>6.0</u>
EBIT/kg	2.5	1.0
ROCE on new volumes	12%	17%

However, this is an important, yet simplified illustration. Volume growth may also come from operational improvements, such as higher survival rates, larger smolt reducing time at sea, better license utilisation and other productivity measures. In such cases, the incremental capital requirement and return profile can be materially different.

11 Barriers to Entry – Licenses

Barriers to Entry – Licenses

Due to biological constraints, seawater temperature requirements and other natural constraints, farmed salmon is only produced in Norway, Chile, Scotland, the Faroe Islands, Ireland, Iceland, Canada, USA, Tasmania and New Zealand.

Atlantic salmon farming began on an experimental level in the 1960s and evolved into an industry in Norway in the 1980s and in Chile in the 1990s.

In all salmon-producing regions, the relevant authorities have a licensing regime in place. To operate a salmon farm, a licence is the key prerequisite. Such licences restrict the maximum production of each company and the industry overall. The licensing regime varies across jurisdictions.

Barriers to Entry – Licenses

11.1 Regulation of fish farming in Norway

License and location

Fish farming companies in Norway are subject to a large number of regulations. The Aquaculture Act (17 June 2005) and the Food Safety Act (19 December 2003) are the two most important laws, and there are detailed provisions set out in the various regulations which emanated from them.

In Norway, a salmon-farming license allows salmon farming either in freshwater (smolt/fingerling production) or in the sea. The number of licenses for Atlantic salmon and trout in seawater was limited to 1,164 in 2023. Such limitations do not apply for freshwater licenses (smolt production), which can be applied for at any time. Seawater licenses can use up to four farming sites (six sites are allowed when all sites are connected with the same licenses). This increases the capacity and efficiency of the sites.

Production limitations in Norway are regulated as "maximum allowed biomass" (MAB), which is the defined maximum volume of fish a company can hold at sea at all times. In general, one license sets a MAB of 780 tonnes (945 tonnes in the counties of Troms and Finnmark). The sum of the MAB permitted by all the licenses held in each region is the farming company's total allowed biomass in this region. In addition, each production site has its own MAB and the total amount of fish at each site must be less than this set limit. Generally, sites have a MAB of between 2,340 and 4,680 tonnes.

New seawater licenses are awarded by the Norwegian Ministry of Trade, Industry and Fisheries and are administered by the Directorate of Fisheries. Licenses can be sold and pledged, and legal security is registered in the Aquaculture Register. Since 1982, new licenses have been awarded only in certain years and growth in biomass is today regulated on the basis of the new system for growth implemented in 2017.

The Norwegian coast is divided into 13 geographical areas of production. The level of sea lice in these areas decide if the MAB can increase (green area +6%), stay the same (yellow area) or decrease (red area -6%) in these areas. Every second year the government announces the conditions for growth on existing and new licenses. Growth through the "Traffic Light System" has been sold by the government to the industry based on an auction process since 2018. The purpose of the auction has been to maximise the proceeds through a competitive closed clock auction by tonnes in all green areas. The average price paid for a new standard license in the auction was NOK 153 million and NOK 171 million in 2018 and 2020, respectively. Total proceeds for the government and local communities were approximately NOK 3.9 billion and NOK 6.9 billion in said years. The Traffic Light System has effectively ensured a form of capturing the resource rent, in exchange for growth. In 2022 the average price for a new license was significantly reduced to NOK 120 million due to the uncertainty in relation to the proposed resource rent tax scheme. In 2023, the auction for the unsold capacity was carried out at an average price of NOK 143 million. Total proceeds amounted to NOK 5.3 billion. During the Traffic Light System for growth in 2024 proceeds amounted to NOK 5.8 billion, with licenses values in the auction averaging NOK 238 million.

Sites complying with very strict environmental standards are offered additional growth. The conditions for this growth are A) below 0.1 lice per fish at every counting for the past two years in the period April 1st to September 30th and B) a maximum of one treatment during the last cycle of production. For sites meeting this standard a maximum of 6% growth is offered, regardless of the general situation in the different production areas. In "red" areas, companies will need to reduce production by 6%.

Barriers to Entry – Licenses

Resource rent tax on aquaculture was introduced in September 2022 with effect from 1 January 2023 and approved by Parliament on 31 May 2023. The resource rent tax rate of 25 percent applies to the production of salmon, trout, and rainbow trout in the sea phase, and implies a marginal tax rate of 47 percent. Activities outside the seawater phase are subject to ordinary corporate tax only. On 5 June 2026, the Norwegian Parliament voted to abolish the aquaculture price council, which sets the baseline for payable resource rent tax, and the current norm-price system for salmon farmers from the 2027 income year. The government will now prepare and bring forward detailed legislative changes.

A tax-free allowance of MNOK 70 is granted at the corporate group level, making the smallest companies exempt from the resource rent taxation. The group definition includes companies with decisive influence over another enterprise by agreement. The tax-free allowance of MNOK 70 must be adjusted by the corporate tax rate of 22 percent, resulting in a net allowance of MNOK 54.6. In addition, the production fee introduced in 2021 has been increased to NOK 0.935/kg salmon produced from 1 January 2024. The production fee will be directly deductible in payable resource rent tax. It is still unclear whether the current auction system for licenses, which takes place every second year, will continue in 2026. At the time of writing, no decision on the Traffic Light System for 2026 has been made by the Ministry of Trade, Industry and Fisheries.

In October 2021, the Government appointed a committee to review the licensing system in the Norwegian aquaculture industry. In September 2023, the committee assessed the objectives for the license regulations, the entirety of the system and how it can be adapted to existing and new challenges. Following the work of the Nøstbakken Committee, the Government decided in December 2023 that they would further review the license regulations and present a proposal to Parliament resulting in a white paper presented in April 2025.

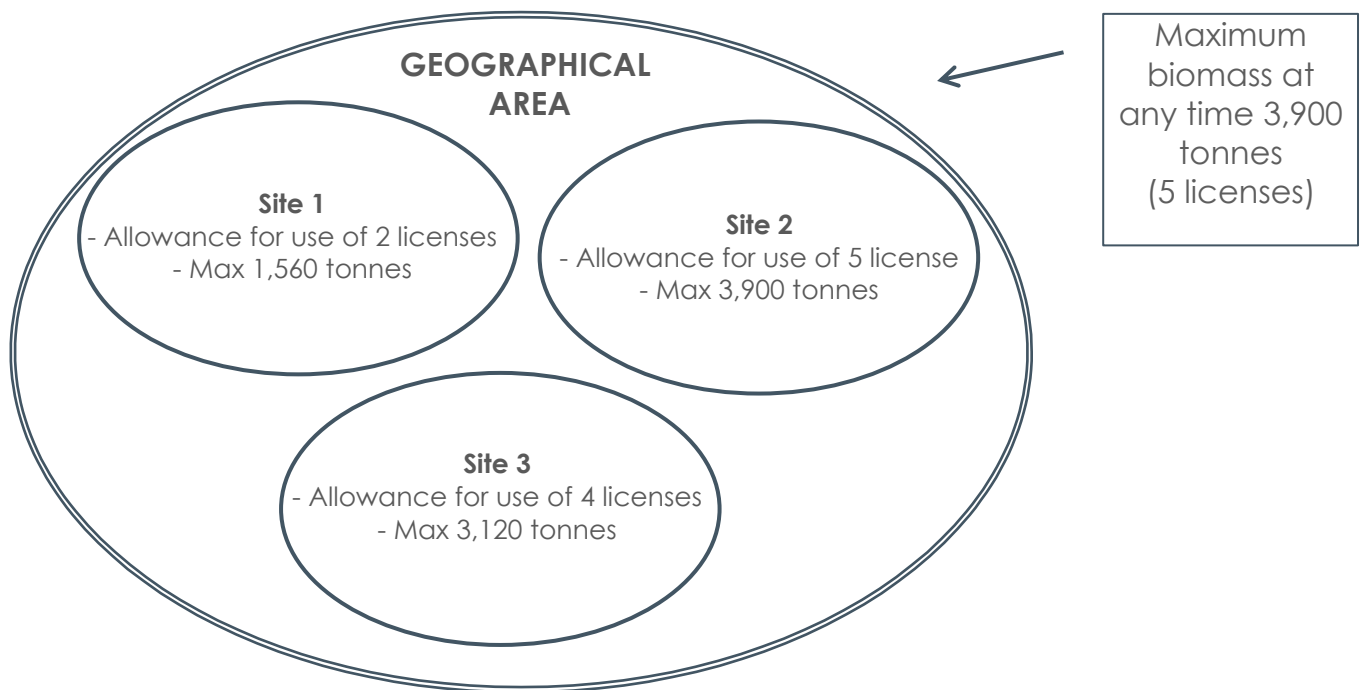

The white paper titled "The Future of Aquaculture – Sustainable Growth and Food for the World" proposed fundamental changes to the regulation of the Norwegian salmon farming sector, including a shift from company-based maximum allowed biomass licences to lice-based quotas to hold farmers directly accountable for sea-lice emissions. In June 2025, the Norwegian parliament's Industry Committee debated the proposals and reached a cross-party compromise where the current traffic-light system and MAB framework is maintained whilst proposals for new regulations and their effects are assessed. The government was also instructed to introduce a new environmental technology scheme in 2025. On 12 June 2025, the Parliament voted in line with the committee's recommendations.

Barriers to Entry – Licenses

Access to Licenses

The figure below depicts an example of the regulatory framework in Norway for one company:

- Number of licenses for a defined area: 5
 - Biomass threshold per license: 780 tonnes live weight (LW)
 - Maximum biomass at any time: 3,900 tonnes (LW)
- Number of sites allocated is 3 (each with a specific biomass cap). In order to optimise production and harvest quantity over the generations of salmon, the license holder can operate within the threshold of the three sites as long as the total biomass in sea never exceeds 3,900 tonnes (LW).
- There are also biomass limitations on the individual production sites. The biomass limitation varies from site to site and is determined by the carrying capacity of each site.

Barriers to Entry – Licenses

Average harvest per standard license 2025

The graph above shows the harvest per license in 2025 for the Norwegian industry as a whole and for the largest listed companies.

Please note that one standard license equates to 780 tonnes in the comparison above. A standard license of 945 tonnes in the counties of Troms and Finnmark has therefore been recalculated to 780 tonnes to make the overview comparable. In addition, a broodstock license is adjusted to 50% of a standard license for all companies whereas development licenses assessed not in commercial use are removed.

Because of the regulation of standing biomass (Maximum Allowed Biomass (MAB)) per license (780 tonnes LW), the production capacity per license is limited. Annual average harvest quantity per license in Norway was 1,212 tonnes GWT in 2025. Larger companies typically have better flexibility to maximise output per license which means that the average harvest figure for the industry as a whole is normally lower than the figure for the largest companies.

Number of grow-out seawater licenses for salmon and trout in Norway:

2021: 1,098

2022: 1,135

2023: 1,164

2024: 1,195

2025: 1,202

Barriers to Entry – Licenses

Estimated MAB-utilisation in Norway 2016-2025

© 2026 Kontali. All rights reserved. Not to be reproduced, shared, or distributed without written consent from Kontali

Maximum allowed biomass for commercial use by the end of 2025 was 1,035,696 tonnes of Atlantic salmon and trout. MAB-utilisation is normally at its highest in October–November, because rate of growth is higher than rate of harvest during the summer. It is at its lowest in April–May due to low growth during the cold winter months. Average utilisation of the MAB was 87% in 2025, up from 85% in 2024.

Barriers to Entry – Licenses

11.2 Regulation of fish farming in Scotland

Licenses and location

In Scotland, instead of a single aquaculture license, permissions are required from a number of organisations before setting up a fish farming site; Planning Permission from the local planning authority, a Marine license relating to navigational considerations from Marine Scotland; an environmental permit from the Scottish Environment Protection Agency (SEPA) and an Aquaculture Production Business authorisation, also from Marine Scotland, all these permissions are required to run concurrently for a farming operation to be licensed. Additionally, a seabed lease from The Crown Estate is required to install and operate a fish farm.

The Maximum Allowed Biomass (MAB) for individual sites is determined based on an assessment of environmental concerns, including the assimilative capacity of the local marine environment to be able to accommodate the fish farm. Setting MAB falls within SEPA's regulatory remit based against published Environmental Quality Standard for water and sediment in order to achieve a licensed discharge. During 2019 SEPA introduced a new regulatory framework for the licensing of marine fish farms in Scotland. This included new limits on the spatial extent of the impact mixing zone around farms, the use of more accurate modelling tools and more enhanced environmental monitoring. MAB is not uniform and varies depending on the site characteristics and location of the fish farm. The combination of the new regulatory standards, the more detailed, accurate modelling approaches supported by enhanced benthic monitoring has enabled the approval of larger farms than would have been traditionally approved previously (i.e., >2,500 tonnes) provided they are appropriately sited in sustainable locations with demonstrably higher assimilative capacity.

The environmental permit from SEPA can be reviewed and MAB reduced in the event of non-compliance with benthic environmental standards and potentially revoked in cases of significant and long-term non-compliance.

The Crown Estate owns and manages most of the seabed around the UK out to a distance of 12 nautical miles. Anyone who develops or operates in UK territorial waters is doing so on Crown Estate property. Because of this, you must apply for a lease from The Crown Estate and pay rent to install, maintain and operate your farm on the seabed. Most existing leases are automatically renewed at the end of their lease period. A Crown Estate lease is generally granted for a period of 25-year period and is dependent on securing Planning Permission.

All new fish farms or alterations to existing fish farms require planning permission. New site applications can take 6 months for planning permission to be granted with the determination period for applications for the environmental license being 4 months, however both can take significantly longer.

Expansion of existing facilities, subject to environmental suitability can be the most efficient route in terms of cost, time and timeline for securing regulatory changes; new sites will take a greater amount of time, reflective of the need for detailed investigations into the characteristics of locations, including collection of environmental data and will be subject to an Environmental Impact Assessment (EIA) to secure planning permission.

An annual rental is levied by the Crown Estate which from 1 January 2023 tracks market price, as 1.0% benchmark of notional business turnover calculated for the harvested production and referenced against the applicable average market price over a 6-month reporting and invoicing period. An increased 1.5% benchmark is now in effect from January 2026. A baseline minimum rent, scaled according to licensed MAB, is applied for calendar years where there has been no harvested production. An escalator is applied which doubles the minimum rent after 4 years of no production and then every two years thereafter where these circumstances persist to discourage "land-banking" with unproductive sites. Nursey sites that yield no

Barriers to Entry – Licenses

harvested production, but which are in productive use are liable for an annual rent equivalent to three times the applicable minimum rent to recognise productive value.

The SEPA environmental permit for an existing fish farm attracts an annual charge calculated according to three elements: activity and environmental components, and a compliance factor. The annual charge can in some cases be >40,000 GBP. Applications fees for a new environmental permit from SEPA are assessed according to the type and scale of aquaculture facility with a new marine finfish farm with a MAB >1500 tonnes would attract the maximum application fee of 38,280 GBP.

The fees for new or modified marine aquaculture site planning applications are set by the Scottish Government and apply across the whole of Scotland. They are based on a combination of the surface area occupied by the surface equipment and the seabed area occupied by the anchors required to maintain the equipment in place. Fee levels are calculated using the following principles: the placing or assembly of equipment in any part of any marine waters for the purposes of fish farming. A fee of 247 GBP for each 0.1 hectare of the surface area of the marine waters to be used in relation to the placement or assembly of any equipment for the purposes of fish farming and a further fee of 92 GBP for each 0.1 hectare of the seabed to be used in relation to such development, subject to a maximum of 30,921 GBP. A reduced fee of 805 GBP applies for certain types of modifications to existing fish farms where "permitted development rights" apply.

Barriers to Entry – Licenses

11.3 Regulation of fish farming in Ireland

Aquaculture in Ireland is licensed by The Minister for Agriculture, Food and the Marine, (MAFM) under the Fisheries (Amendment) Act, 1997 and its associated Regulations which have been amended to give effect to various EU environment protection Directives. The licensing process is complex.

The Aquaculture and Foreshore Management Division, (AFMD) of the Department manages the processing of aquaculture licenses on behalf of the Minister. The Marine Engineering Division (MED) of the Department undertakes site mapping and provides certain technical advice on applications as well as undertaking certain post-licensing inspection duties. The Marine Institute (MI) provides scientific advice on a range of marine environment and aquaculture matters and in the case of applications which require Appropriate Assessment (AA) under EU Birds and Habitats Directives. Advice is also provided by Bord Iascaigh Mhara (BIM) and the Sea Fisheries Protection Authority (SFPA). The National Parks and Wildlife Services (NPWS) are consulted in relation to habitat protection. Inland Fisheries Ireland (IFI), An Taisce, Irish Water, Failte Ireland, the Department of Housing, Local Government and Heritage (DHLGH), the Marine Survey Office (MSO) and the Commissioners of Irish Lights (CIL) are also consulted. Where relevant, the Local Authority and/or Harbour Authority are consulted. Land based fin fish units also require planning consent from the local authority. All applications are released for public consultation and comment.

An Environmental Impact Assessment Report (EIAR) is mandatory for marine finfish applications and applicants are required to submit an EIAR with their initial applications. The obligation to carry out an Appropriate Assessment (AA) applies if the application is within a Natura 2000 site or likely to impact on a Natura 2000 site. Decisions of the Minister in respect of aquaculture license applications, including license conditions, may be appealed to the Aquaculture Licenses Appeals Board (ALAB). ALAB can confirm, refuse or vary a decision made by the Minister or issue licenses itself under its own authority.

Licenses are typically issued for 10 years. The 1997 Act provides for license duration of up to 20 years. Foreshore (seabed) leases and licenses are companion consents to Aquaculture Licenses. Foreshore Acts allow for leases and licenses to be granted for terms not exceeding 99 years, respectively. Terms of current licenses vary between harvest output (tons) per annum, smolt number input, maximum number of fish on site or a combination of these. Prior to expiry of a license, an application for renewal of the license must be made.

Currently the processing of a marine fin fish license application takes at least 954 weeks. Most licenses will be appealed to ALAB which can take at least a further 272 weeks to determine. The process of renewing expired fin fish licenses takes as long as a new application. However, in the past three years there is evidence of license applications being dealt with by the licensing authority in a more proactive manner with gathering momentum in engagement with license applicants.

In 2017, the Minister for Agriculture, Food and Marine initiated an independent review of the Aquaculture licensing system in Ireland. The report of this review was published in May 2017 with the overarching conclusion, that a root-and-branch reform of the aquaculture license application processes is necessary which encompasses a further 30 recommendations.

Annual fin fish culture license fees for a marine based fin fish site are €6.35 per tonne for the first 100 tonnes plus €6.35 for each additional tonne. Foreshore rental fees are charged at €63.49 for up to and including 5 hectares of foreshore with each additional hectare up to 10 ha at €31.74 and each additional hectare >10 and up to 20 at €63.49. Annual culture license fee for a land-based site is €127.97 per annum.

Barriers to Entry – Licenses

11.4 Regulation of fish farming in Chile

License and location

In Chile licensing is based on two authorisations. The first authorisation is required to operate an aquaculture facility and specifies certain technical requirements. It is issued by the Undersecretaries of Fisheries and Aquaculture (under the Ministry of Economy). The second authorisation relates to the physical area which may be operated (or permission to use national sea areas for aquaculture production). This is issued by the Undersecretaries for Armed Forces (Ministry of Defence). The use of the license is restricted to a specific geographic area, to defined species, and to a specified limit of production. The production limits are specified in Environmental and Sanitary Resolutions for the issued license. Under certain conditions, owners can choose to reduce their whole stocking, producing at maximum density (17kg/m³ for Atlantic salmon), or to maintain or increase their stocking, using a limited density (from 4 to 17 kg/m³ for Atlantic salmon) determined by productive, sanitary and environmental conditions of each neighbourhood, any increase over previous stocking numbers means going to 4 kg/m³. Owners can choose only one alternative to stock each semester. From January 2021, all producers have the option to increase the smolt stocking based on a combined score of fish health parameters, related to losses, sea lice treatments and antibiotic use. The individual company's performance on the parameters in the previous period will determine the size of the potential increase in the next smolt stocking. A positive assessment will result in an increase of 3%, 6% or 9%, while a negative assessment will result in a reduction of 3%, 6% or 9%. For example, if antibiotic consumption is below 300 g / tonne, mortality is less than 10% and the indicator related to bath treatments against *Caligus* is below 50%, the model will allow farmer the option to grow by 6% in the next stocking.

Access to Licenses

The trading of licenses in Chile is regulated by the General Law of Fisheries and Aquaculture (LGPA) and controlled by the Undersecretaries of Fisheries and Aquaculture of the Ministry of Economy. Aquaculture activities are subject to different governmental authorisations depending on whether they are developed in private fresh water inland facilities (i.e. hatcheries) or in facilities built on public assets such as lakes or rivers (freshwater licenses) or at sea (seawater licenses).

To operate a private freshwater aquaculture facility requires ownership of the water-use rights and holding of environmental permits. Environmental permits are issued when operators demonstrate that their facilities comply with the applicable environmental regulations.

Licenses for aquaculture activities in public assets are granted based on an application, which must contain a description of the proposed operations, including a plan for complying with environmental and other applicable regulations. Licenses granted after April 2010 are granted for 25 years and are renewable for additional 25-year terms. Licenses granted before April 2010 were granted for indefinite periods. License holders must begin operation within one year of receiving a license and once the operation has started, the license holder cannot stop or suspend production for a period exceeding two consecutive years. Subject to certain exceptions, license holders must maintain minimum operational levels of not less than 5% of the yearly production specified in the RCA (Environmental Qualification Resolution).

License holders must pay annual license fees to the Chilean government and may sell or rent their licenses. For the moment, no new licenses will be granted in the most concentrated regions, Regions X, XI, and XII (Chile is made up of 16 administrative regions).

Barriers to Entry – Licenses

11.5 Regulation of fish farming in Canada

License and location

Fish farming companies in Canada are subject to varying regulations depending on the geographical area where they operate. To operate a marine fish farm site, provincial and/or federal authorisations are required. The principal Federal laws are the Fisheries Act, the Canadian Navigable Waters Act, The Health of Animal Act, and the Species at Risk Act. The Aquaculture Activities Regulations (AAR) are national regulations that apply throughout Canada. Each province has specific Acts and Regulations that also apply. The three primary marine fish farming areas in Canada are the provinces of: Newfoundland and Labrador, New Brunswick and British Columbia.

In Newfoundland and Labrador and New Brunswick, the Provincial government is the primary regulator and licensing authority. The Provinces regulate the activity and operations of aquaculture and issue the Aquaculture Licence, Crown Land lease and Water Use Licence (Newfoundland and Labrador only) where fish farms are located. In Newfoundland and Labrador, the Crown Land Lease for the site is issued for 50 years, the Aquaculture Licence is issued for 6 years, and the Water Use Licence is issued for 5 years. In New Brunswick, individual sites are typically granted a lease for 20 years. Farms in New Brunswick are also issued an Approval to Operate with a 5-year term limit by the provincial Department of Environment and Local Government. In Newfoundland and Labrador new licence application fees and annual licence fees are \$145/hectare (i.e., \$5,075 for a 35 hectare sea farm); Crown land application fees and title are \$150 and \$300 respectively, and annual rental fee \$8/hectare (i.e. \$280 +HST for a 35 hectare sea farm); and water use licence fees are \$300 and annual marine water use charges are \$1,000. In New Brunswick the application fee is \$2,400 and the application fee for designation of aquaculture land is \$500, and annual the rent for a lease is \$250/hectare (i.e., \$8,750 for a 35-hectare farm).

In British Columbia, Federal and Provincial authorisations are required to operate a marine fish farm site. The Federal Government regulates the activity and operations of aquaculture while the Provincial Government administers the Crown lands where fish farms are located. The Province grants a licence to occupy an area of the ocean associated with the individual fish farming site. The tenure encompasses the rearing pens, ancillary infrastructure and all moorings. Individual site tenures have a specific timeline ranging from five to twenty years. The term of tenure is based upon the provincial policy at the time of offer. In 2024, the annual fee for a typical 35 hectares tenure is \$22,000 CAD per year. This fee is calculated based on the tenure size and a provincially indexed land value. Each tenure /licence of occupation continues once the term has expired. After the tenure term has expired, it becomes a month-to-month occupancy until it is either renewed or returned to the Crown. It is uncommon that a tenure is not renewed, however breaches to a tenure agreement could result in non-renewal

The production limitations in Canada are regulated as either a Maximum Allowable Biomass (MAB) (standing biomass) or as a fixed number of smolt per production cycle. MAB is determined by the carrying capacity of each licensed site in British Columbia and ranges from 600–5,200 tonnes, with an average of approximately 3,000 tonnes. In the provinces Newfoundland and Labrador, and New Brunswick, production is relegated through a maximum number of smolt per cycle. Farms are typically licensed for 600,000–2,000,000 smolt per cycle in Newfoundland and Labrador, and 250,000–600,000 smolt per cycle in New Brunswick.

In British Columbia, the Federal Government issues an Aquaculture Licence with regulatory conditions that a farm must meet. The Aquaculture licence conditions are linked to national legislation. Aquaculture conditions of licence specify the species farmed, the Maximum Allowable Biomass (MAB), the type of rearing equipment, reporting requirements and the allowable environmental impact. The annual licence fee (2026) is † \$3.05 CAD per ton of MAB for operational sites.

Barriers to Entry – Licenses

Access to Licenses

All permits and licences in British Columbia require support by First Nations and local stakeholders. The time to acquire licences for a new farm can vary from one to several years. The cost for preparing a new site application averages approximately \$500,000 CAD. The location of aquaculture farms is regulated by both the Provincial and Federal governments. The Province regulates the land use, and the Federal government regulates navigation and sets out site specific requirements to limit impacts to sensitive species and habitats. Companies with the support of local First Nations can still obtain new tenures.

All farming licences were issued in 2024 for a 5-year term. During this period the government committed to the development of a transition plan for salmon farming in British Columbia. New licences will only be considered by the federal government if the application includes advanced barrier technology as the main containment infrastructure. This has not been achieved in practice; Mowi Canada West continues to work with First Nations and government to secure a future for sustainable salmon farming in British Columbia.

In Newfoundland and Labrador (NL), proponents must submit a sea cage licence application to the Newfoundland and Labrador Department of Fisheries, Forestry and Agriculture for each new or acquired marine site. In New Brunswick, companies must submit an Aquaculture licence Application for Marine Sites to the Department of Agriculture, Aquaculture and Fisheries. It takes about twelve months to transition an existing site to a new owner, and approximately 18–24 months for a new application in both places (including collection of environmental data). This includes obtaining all necessary approvals and licences, and a review from The federal Department of Fisheries and Oceans. Fisheries and Oceans Canada utilise the Canadian Science Advisory Secretariat (CSAS) review process to prepare science advice for DFO Aquaculture Management; advice is then provided to the Provinces of NL& NB to inform their licensing decision. Consultation with residents, towns, development groups and commercial/recreational fishermen is required. In Newfoundland and Labrador, all new sites of the same company must be 1 km apart, 5 km if sites are operated by different companies. Consultations with First Nations is now required in both New Brunswick and Newfoundland and Labrador prior to submission of the application. Any changes to the existing footprint (through changes to lease boundaries or increases to biomass limits) may require habitat surveys, depositional modelling and / or amendment of Transport Canada approvals.

In Newfoundland and Labrador, Provincial approvals can be assigned to a different operator through a government sub-lease assignment process, however, licences are not transferable. A company may transfer licences to another company providing the rationales for the assignment are supported by the government processes in New Brunswick.

Barriers to Entry – Licenses

11.6 Regulation of fish farming in the Faroe Islands

License and location

Fish farming companies in the Faroe Islands are subject to extensive regulation. The most important legislative instruments are the Aquaculture Act (Act No. 83 from 25 May 2009 with latest amendments from 2023), the Environmental Act (Act No. 134 from 29 October 1988 with latest amendments from 2021), the Food Safety Act (Act No. 58 from 26 May 2010 with latest amendments from 2017) and the Parliamentary Act No. 65 from 30 May 2024 on a harvesting fee.

In addition to the above-mentioned acts, several Executive Orders with more detailed provisions covering fish farming have been issued under the provisions of the acts.

The right according to a specific license is provided for a specific geographic area and with a limit of production specified in the individual license. Production and stocking density limit is specified in an Environmental and Sanitary Resolution issued for each specific license. The density limit may depend on production conditions as well as sanitary and environmental conditions.

The size of the area and density limits etc. for each of the 20 sea licenses vary greatly. Production limitations in the Faroes are not regulated through limits on "maximum allowed biomass", MAB. As a consequence, MAB for salmon farms varies between 1,200 tonnes and 5,800 tonnes a year per license, depending on site characteristics and the geographic location of the individual farm.

In 2012 and 2018 the Government of the Faroe Islands announced revised aquaculture regulations with the aim of securing sustainable growth in the industry and in order to implement anti-trust regulations.

Mowi Faroes is first and foremost affected by the anti-trust regulations in the Aquaculture Act. These rules set a cap of 20% for either direct or indirect foreign ownership in Faroese fish farming companies. If the limit is exceeded with regard to a fish farming company, the company must adjust its ownership to be within the limit within a short deadline set by the authorities or face possible loss of the right to conduct fish farming activities.

Mowi Faroes is 100% owned by Mowi ASA (NO). This ownership is protected by transitional provisions in the Aquaculture Act, securing that the company can remain owned by a foreign company and nonetheless keep its licenses. The consequence for Mowi Faroes of the Anti-trust regulations is that the company cannot expand its business with additional commercial licenses to farm fish in the sea. Mowi Faroes can however apply for development licenses and licenses on land.

It is stipulated in the Aquaculture Act that a fish farming company cannot hold more than 50% of the total sea licenses. The new restrictions do not apply to licenses held by each individual company today, but the new regulations specify that Mowi Faroes can keep its 3 seawater licenses and 1 smolt license, even though the company does not comply with the new cap on foreign-held capital.

Access to Licenses

In order to conduct fish farming activities in the Faroe Islands, the fish farming company must obtain authorisation from Heilsufrøðiliga Starvsstovan (The Faroese Food and Veterinary Authority) to operate an aquaculture facility. The authorisation specifies certain technical requirements with regard to conducting fish farming activities.

Fish farming companies with the above-mentioned authorisation can apply for licenses to conduct fish farming activities from the Ministry of Foreign Affairs and Trade. New sea licenses

Barriers to Entry – Licenses

can be awarded by the Ministry of Foreign Affairs and Trade. There are today a limit of 20 commercial seawater licenses and no limit for licenses on land. If new licenses are to be awarded, they may be awarded through auction.

An application for a seawater license must contain a description of the proposed operations, including a plan for complying with environmental and other applicable regulations.

The government of the Faroe Islands in April 2018 announced a new category of licenses, i.e. development licenses. Development licenses are intended to motivate investment in new fish farming technologies. Due to the anti-trust regulations, Mowi Faroes can only obtain development licenses, as the limits regarding foreign ownership do not apply to such licenses.

Licenses are granted for 12 years and are renewable for additional 12-year term. License holders must pay an annual fee of DKK 12,000 for each individual license.

Licenses can be sold and pledged, and legal security is perfected by registration with the Land Registry. Licenses may be withdrawn in cases of material breach of conditions set out in the individual license or in the aquaculture or environmental legislation.

Fish farming companies must also pay a harvesting fee based on the harvesting of farmed fish. The fee is based on the weight of gutted fish harvested in a month, multiplied by the average international market price in the same month.

From 1 January 2025 the harvesting fee has been calculated according to the formula below:

The system is called a bipartite system, which consists of a harvesting fee and a special tax on profits of fish farming companies.

The harvesting fee starts at 0.5 percent and end at 7.5 percent, set relative to the international salmon price. The special tax will be 8 percent of the profits of fish farming companies.

The payment has been set as follows:

P = average international market price in DKK per kg.
K = average weight of gutted fish harvested in a month.

- If P is lower than K, the payment is 0.5%.
- If P is higher than or the same as K, but lower than K + DKK 5, the payment is 2.5%.
- If P is higher than or the same as K + DKK 5, but less than K + DKK 15, the payment is 5%.
- If P is higher than or the same as K + DKK 15, but less than K + DKK 20, the payment is 7.5%.

The special tax:

The fish farming companies pay an extra special tax on their taxable income from their activities from the production of fry until sea production and harvesting.

Calculation of Production Costs

Production costs have been calculated and set every three years based on the accounts of the fish farming companies. In the intervening years, production costs will be indexed based on the ordinary price index and the price of feed. This is done as follows:

- a) Year 1 (2025) production costs, K, is calculated based on the latest audited annual accounts of the fish farming companies.
- b) Year 2 production costs are indexed based on the price index, which shall weigh 50%, and the increase in the cost of feed, which shall weigh the remaining 50%.
- c) Year 3 production costs are indexed in the same way as in year 2.
- d) Year 4 production costs again be calculated based on the latest audited accounts of the fish farming companies.

Barriers to Entry – Licenses

11.7 Regulation of fish farming in Iceland

Licenses and location

Salmon farming companies operating in Iceland need two types of licenses to obtain a right to farm salmon: an industrial license from the Environment Agency, and a production license from the Food and Veterinary Authority. The industry is governed by the Ministry of Industries and is subject to extensive regulation. The most important laws and regulations include the Aquaculture Act no. 71/2008 with later amendments, most importantly Act 101/2019, as well as regulation on Aquaculture no. 540/2020. Other relevant laws and regulations include Regulation no. 550/2018 on Industrial Emissions and Pollution Control, Act no. 36/2011 on Water Management, Act no. 33/2004 on Marine and Coastal Antipollution Measures, Act no. 89/2019 on The Collection of Fees for Aquaculture in the Sea and the Aquaculture Fund and Act no. 111/2021 on Environmental Impact Assessment of Projects, Public Plans and Programmes.

Before applying for a license in Iceland, salmon farmers are required to undertake an environmental impact assessment (EIA) of their production plans, overseen by the Housing, Construction and Planning Authority. An EIA involves the thorough analysis and evaluation of potential environmental effects stemming from the proposed salmon farming operations that are likely to affect the surroundings. This entails examining the environmental impact, assessing the significance of the effects, and suggesting mitigating measures. The results of an EIA may necessitate adjustments to the proposed farming operations, aimed at minimising their adverse environmental impact. Throughout the EIA and licensing procedure, all proposed operations and applications are subject to public consultation and comment.

Once an EIA has been finalized, salmon farming companies operating in Iceland must acquire two types of licenses to commence salmon farming: An industrial license from the Environmental Agency (UST) and a production license from the Food and Veterinary Authority (MAST). For these licenses to be granted, the EIA must ascertain that the proposed production aligns with various environmental and fish welfare legislation and regulations. Companies apply for both permits simultaneously, with the process overseen by MAST, with licenses valid for up to 16 years.

Access to licenses

Farming is allowed in the West Fjords and in the East Fjords of Iceland with possible expansion into a single fjord (Eyjafjörður) in the north-east of the country. The rest of the coastline is closed for farming. Since new legislation in 2019 all new sites for farming are to be auctioned off with the exception of applications that were applied for before the change. Before areas are put up for auction the Icelandic Maritime Agency (i. Hafrannsóknunarstofnun) must produce an estimate of the allowed biological load, so-called load-bearing capacity (i. Burðarþolsmat) and an estimate on how much farming of fertile salmon is allowed in a given area without risk for genetic mixing in rivers with wild salmon stocks, so called risk assessment (i. Áhættumat).

As of April 2026, the load-bearing capacity assessment for Iceland stands at 144,500 tonnes and the risk assessment for genetic mixing stands at 106,500 tonnes (maximum allowed biomass of fertile salmon). Issued licenses amount to 105,750 tonnes MAB whereof 93,000 tonnes are fertile salmon, 9,300 tonnes are sterile salmon, and 3,450 tonnes are for trout. Of the 14,500 tonnes of fertile salmon available, 6,500 tonnes have been applied for, and the remaining 8,000 tonnes are available to be auctioned off, all in fjords with existing farming, making entry for new farmers difficult. Additional available locations within allowed farming areas are awaiting load-bearing assessments in accordance with Act 101/2019, however, no load-bearing capacity assessments have taken place in Iceland since the enactment of the amendment in 2019.

Farming areas as defined by the load-bearing capacity assessment can contain multiple license holders. Each license is fixed to a pre-determined location within the area, defined by GPS co-ordinates and usually comprising 2–3 sites on one license within the same water system. Farming locations are fixed within license boundaries and the total biomass farmed in the

Barriers to Entry – Licenses

designated area cannot exceed the load-bearing capacity of that area. License holders are subject to regular audits by both MAST and UST.

In March 2026 the Minister of Industries put forward a new bill on fish farming in Iceland with many new requirements. It remains uncertain whether the bill will be approved and with or without changes.

Taxes and Fees

A production tax is being introduced to the industry from 2020 to 2026 with 1/7 less discount every year. For 2024 the highest step of the tax ladder was increased from 3.5% to 4.3% of Nasdaq prices. Farmers also pay a harbour fee at the harbour where fish is harvested, appropriately 0.7%–0.8% of monthly Nasdaq prices and a fee to the environmental fund, equivalent to approx. 3,700 ISK \approx 284 NOK per tonne license. All this adds up to some ~6% of turnover when fully implemented.

The current tax system is:

0.5% of Nasdaq price when prices are lower than 4.3 EUR/kg;
2.0% of Nasdaq price when prices are between 4.3 EUR/kg and 4.8 EUR/kg;
4.3% of Nasdaq price when prices are above 4.8 EUR/kg.

The farming fee for 2026 is 41.66 ISK/kg \approx 3.2 NOK/kg.

The fee is based on previous year average prices. In 2026 tax is paid of the volume for 2026 and based on average Nasdaq salmon prices for 2025.

The Fishery Directorate (i. Fiskistofa) is responsible for collecting the fee in two instalments per year. As mentioned above, all new licenses will be auctioned off, however details of the auction process remain unclear as of now.

12 Risk Factors

Risk Factors

12.1 Salmon health and welfare

Maximising survival and maintaining healthy fish stocks are primarily achieved through good husbandry and health management practices and policies, which reduce exposure to pathogens and the risk of health challenges. The success of good health management practices has been demonstrated on many occasions and has contributed to an overall improvement in the survival of farmed salmonids.

Fish health management plans, veterinary health plans, biosecurity plans, risk mitigation plans, contingency plans, disinfection procedures, surveillance schemes, as well as coordinated and synchronised zone/area management approaches, all support healthy stocks with a strong emphasis on prevention through biosecurity, coordinated area management and vaccination.

Prevention of many diseases is achieved through vaccination at an early stage and while the salmon are in freshwater. Vaccines are widely used commercially to reduce the risk of health challenges. With the introduction of vaccines, a considerable number of bacterial and viral health issues have been effectively controlled, with the additional benefit that the quantity of licensed medicines prescribed in the industry has been reduced.

In some instances, medicinal treatment is still required to avoid mortality and for the well-being and welfare of the fish. Even the best managed farms may have to use licensed medicines from time to time, if other measures are not sufficient. For several viral diseases, no effective vaccines are currently available.

Risk Factors

12.2 Most important health risks to salmon

Sea lice: There are several species of sea lice, which are naturally occurring seawater parasites. They can infect the salmon skin and if not controlled they can cause lesions and secondary infection. Sea lice are managed through an integrated pest management approach combining good husbandry and operational practices, barrier technologies (e.g. skirts and submergence systems), lasers, mechanical removal systems and, where necessary, licensed medicines. Cleaner fish are also used in some regions as part of the overall sea lice management strategy, while continued development and adoption of alternative preventive and non-medicinal control methods are expected to reduce reliance on their use over time.

Cardiomyopathy syndrome (CMS): CMS is a chronic disease that can develop over several months and is caused by the piscine myocarditis virus (PMCV). Mortality typically occurs in large seawater fish. A typical disease event can last one to six months. Control is achieved mainly by good husbandry and management practices and keeping the fish in conditions that satisfy their biological needs for food, clean water, space and habitat.

Salmonid Rickettsial Septicaemia (SRS): SRS is caused by intracellular bacteria. It is a major health challenge in Chile but has also been increasingly reported in Scotland and Ireland, while only sporadic cases have been observed in Norway. It causes lethargy and appetite loss and can result in elevated mortality. SRS is partly controlled through vaccination, although medicinal intervention may also be required.

Heart and Skeletal Muscle Inflammation (HSMI): HSMI is currently reported in Norway and to a lesser extent Scotland. Symptoms of HSMI are reduced appetite, abnormal behaviour and in most cases low mortality. HSMI generally affects fish in their first year in sea and control is achieved mainly by good husbandry and management practices.

Infectious Salmon Anaemia (ISA): ISA is caused by the ISA virus and is widely reported. It is a contagious disease that causes lethargy and anaemia and may lead to significant mortality in seawater if not appropriately managed. Control of ISA is achieved through culling or harvesting of affected fish and the application of stringent biosecurity and mitigation measures. Vaccines are available and are in use in areas where ISA is considered to represent a risk.

Gill Disease (GD): GD is a general term used to describe gill conditions occurring in seawater. It is increasingly recognised as a multifactorial condition involving infectious agents such as amoebae, viruses and bacteria together with environmental stressors including algae and jellyfish. The interactions between these factors are not yet fully understood and remain an important area of research.

Risk Factors

12.3 Fish health and vaccination (Norway)

Production and use of antibiotics in Norway

The incidence of bacterial disease events increased in the 1980s. In the absence of effective vaccines, the use of approved antimicrobial medicines reached a maximum of almost 50 tonnes in 1987. Following the introduction of effective vaccines against the main bacterial challenges at the time, the quantity of antimicrobials used in the industry declined significantly to less than 1.4 tonnes (by 1994) and has since then continued to be very low. These developments, along with the introduction of more strict biosecurity and health management strategies, allowed for further expansion of the industry and an increase in production.

During the last two decades, improved husbandry, health management practices and vaccination have enabled effective control of many important diseases in Norway, Scotland and Canada. Fish health and survival remain influenced by a combination of infectious, environmental and production-related factors. In Chile, Salmonid Rickettsial Septicaemia (SRS) remains one of the most important health challenges affecting survival.

Source: Kontali Analyse, Norsk Medisinaldepot, Norwegian Institute of Public Health

Risk Factors

12.4 Research and development

Fish Welfare and Robustness

- Development of better solutions for prevention and control of infectious diseases
- Minimisation of production-related disorders
- Optimisation of smolt quality
- Real-time monitoring of fish welfare
- Monitoring and mitigation of plankton and jellyfish
- Automated plankton and jellyfish monitoring

Product Quality and Safety

- Continuously develop better technological solutions for optimised processing, packaging and storage of products, while maintaining consistently high quality.

New Growth

- Development of methods to reduce production time at sea
- Production in more exposed areas
- Production in closed sea-going units

Production Efficiency

- Development of cost effective, sustainable and healthy salmon diets which ensure production of robust fish
- Identify the best harvesting methods, fillet yield optimisation and the most efficient transport and packaging solutions
- Net solutions and antifouling strategies
- Development of AI-based tools for value chain optimisation and accelerating seawater-phase production efficiency
- Predictive analysis and AI-assisted decision support for early detection of fish health and welfare risks

Footprint

- Develop, validate and implement novel methods for sea lice control
- Reduce dependency on licensed medicines and limit the discharge of medicinal residues
- Escape management and control
- ASC implementation; R&D projects that facilitate and make ASC implementation more efficient

According to Zacco and Hamsø (Norwegian patent offices), the rate of patenting in the salmon farming industry has increased significantly over the past two decades. Considerable R&D activity is taking place across several areas, with the most notable developments occurring in feed, sea lice control and vaccines, driven by large global players. Most producers in the industry are relatively small and lack the capital required to undertake and manage major R&D initiatives. This is expected to change as industry consolidation continues.

Source: Kontali Analyse, Norsk Medisinaldepot, Norwegian Institute of Public Health

Risk Factors

Smolt, on-growing production and processing

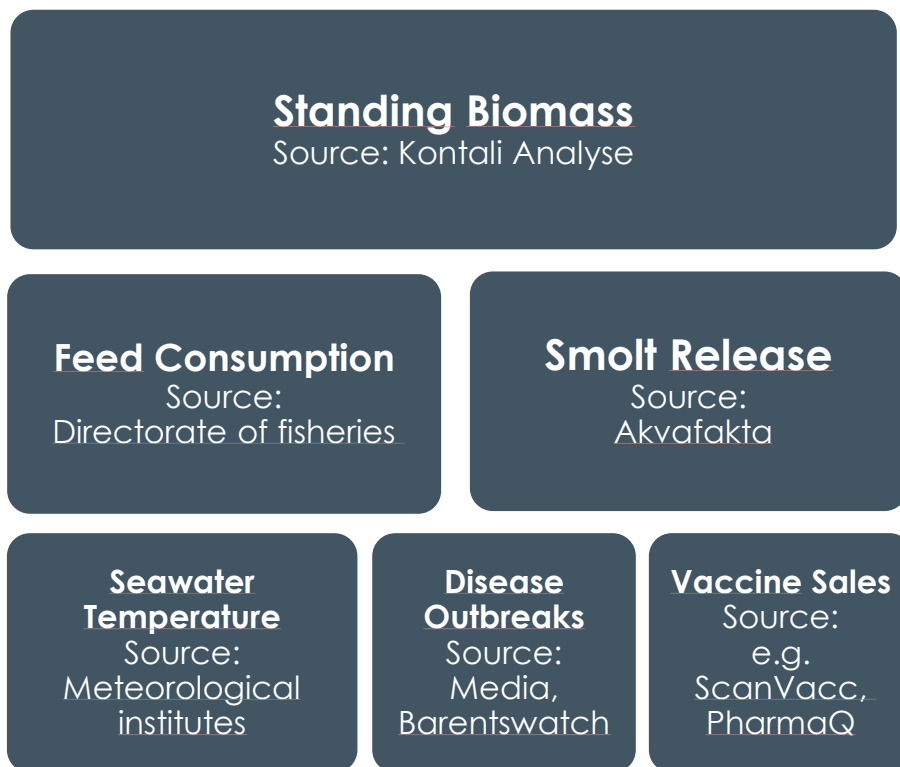

Much of the technology used in these phases is commercially available, although continuous innovation and technological development are driving significant advances. Technology providers and producers are becoming increasingly advanced and skilled, with innovations in automation, digitalisation and fish health management supporting improvements in production efficiency, fish welfare and sustainability.

13 Indicators Determining Harvest volumes

Indicators Determining Harvest volumes

13.1 Projecting future harvest volumes

The three most important indicators for future harvest volumes are standing biomass, feed consumption and smolt release. These are good indicators for medium- and long-term harvest, while the best short-term indicator is standing biomass categorised by size. As harvested size is normally above 4 kg, the available biomass of this size class is therefore the best estimate of short-term supply.

If no actual numbers on smolt releases are available, vaccine sales could be a good indicator of number of smolt releases and when the smolt is put to sea. This is a good indicator of long-term harvest volumes as it takes up to 2 years from smolt release to harvest.

Variation in seawater temperature can materially impact the length of the production cycle. A warmer winter can for example increase harvest volumes for the relevant year, partly at the expense of the subsequent year.

Disease outbreaks can also impact harvest volume due to mortality and growth slowdown.

Indicators Determining Harvest volumes

13.2 Yield per smolt

© 2026 Kontali. All rights reserved. Not to be reproduced, shared, or distributed without written consent from Kontali

Yield per smolt is an important indicator of production efficiency. Due to the falling cost curve and the discounted price of small fish, the economic optimal harvest weight is in the area of 4–5 kg (GWT). The number of harvested kilograms yielded from each smolt is impacted by disease, mortality, temperatures, growth attributes and commercial decisions.

The average yield per smolt in Norway is estimated at 3.51 kg (GWT) for the 24 Generation.

In 2010 and 2011 the Chilean salmon industry performed well on fish harvested, due to the low density of production (improved yield per smolt). In line with increased density in subsequent years, biological indicators deteriorated. In 2016, an algae bloom caused high mortality, and the Chilean salmon industry started to rebuild its biomass once again and improved yield per smolt. The yield per smolt increased in Chile for 24G to 4.16 kg (GWT) from 23G's 3.99 kg (GWT).

Average yield in the UK, North America and Faroe Islands for 23G is estimated at 3.19 kg, 3.09 kg and 4.96 kg, respectively.

Source: Kontali Analyse, Mowi

Indicators Determining Harvest volumes

13.3 Development in biomass during the year

© 2026 Kontali. All rights reserved. Not to be reproduced, shared, or distributed without written consent from Kontali

Due to variations in seawater temperature during the year, the total standing biomass in Europe has a S-curve, which is at its lowest in May and at its peak in October. The Norwegian industry is focused on minimising natural fluctuations as license constraints put a limit on how much biomass can be in sea at the peak of the year.

In Chile the situation is different due to its more stable seawater temperature and opposite seasons (being in the Southern hemisphere). A more consistent water temperature allows for smolt release throughout the year and enables more uniform utilisation of facilities.

14 Secondary Processing (VAP)

Secondary Processing (VAP)

In processing we distinguish between primary and secondary processing.

Primary processing is slaughtering, gutting and pre-rigor filleting. A head-on gutted salmon (HOG) packed in a standard box is normally the point in the value chain at which standard price indices are established.

Secondary processing includes post-rigor filleting, fillet trimming, portioning, producing different fresh cuts, smoking, marinating or breading. Depending on the setup of the processing plant, products are fresh packed with Modified Atmosphere (MAP), vacuum packed or frozen and stored for distribution.

Products that have been secondary processed are called value-added products (VAP), as they represent additional value to retailers, foodservice operators and, ultimately, the final consumer.

Secondary Processing (VAP)

14.1 European value-added processing (VAP) industry

- A total value of > EUR 25 billion
- Employees > 135,000
- Extremely fragmented – more than 4,000 companies
- About 50% of all companies have fewer than 20 employees
- Traditionally EBIT-margins have been between 2% and 5%
- The average company employs 33 people and has a turnover of EUR 4.2 million

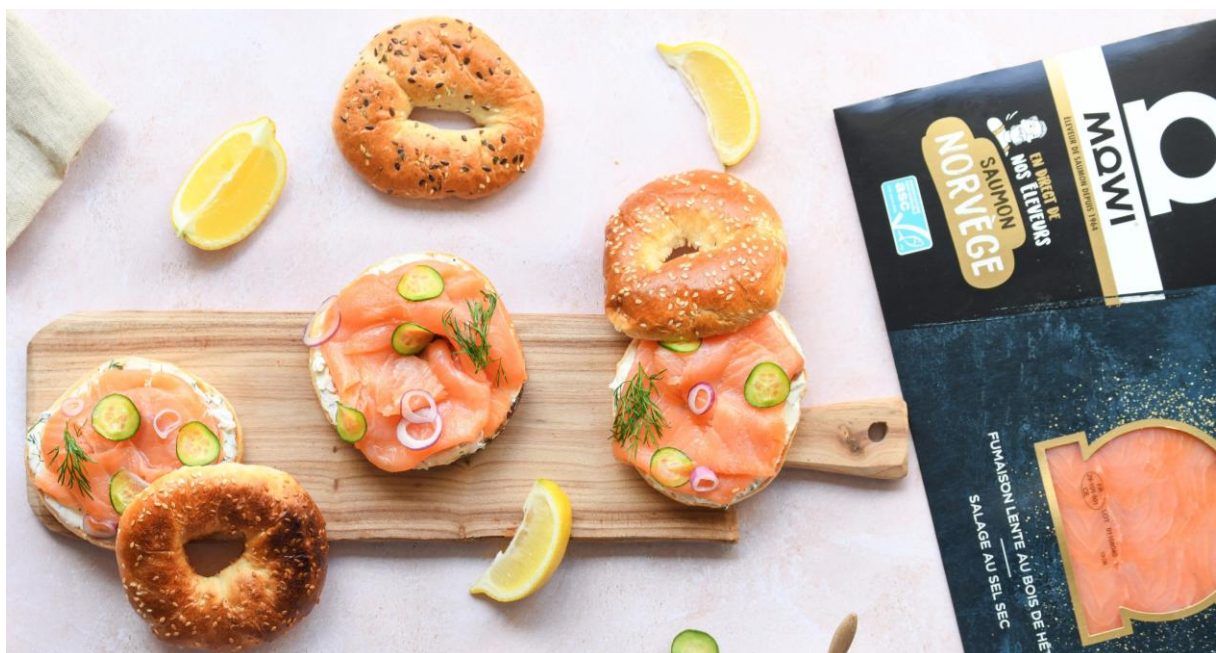

■ Fish ■ Others ■ Shellfish and mussels

The seafood industry in Europe is fragmented, with more than 4,000 players. Most companies are small, but several large companies are active in the secondary processing industry, including Mowi, Icelandic Group, Deutsche See, Caladero, Royal Greenland, Labeyrie, Parlevliet & Van der Plas and Lerøy Seafood. Some of these companies are integrated into fish farming or wild catch, while others source raw materials externally for processing.

Most of the largest players base their processing on Atlantic salmon, producing smoked salmon, salmon portions or ready meals with different packing techniques. Others are into white fish processing.

Consumers are willing to pay for quality and added value. This means that we expect to see an increase in demand for healthy convenience products such as ready-to-cook fish, together with a packing trend towards MAP as this maintains the freshness of the product longer for than fish sold in bulk.

Secondary Processing (VAP)

14.2 Market segment

Market segment in the EU (2025E)

© 2026 Kontali. All rights reserved. Not to be reproduced, shared, or distributed without written consent from Kontali

In the EU, around 75% of Atlantic salmon supply was sold through retail channels, while the remainder went to foodservice establishments. The foodservice share returned to pre-pandemic levels in 2022. Approximately 75% of the products were sold fresh. Fillets represented the largest product category with a market share of 40%, followed by smoked salmon and Other VAP products.

Secondary Processing (VAP)

14.3 The European market for smoked salmon

Est. % share of smoked salmon market, EU+UK, 2025E

© 2026 Kontali. All rights reserved. Not to be reproduced, shared, or distributed without written consent from Kontali

Smoked salmon is the most common secondary-processed product after fillets. The European market for smoked salmon was estimated to be 330,000 tonnes GWT in 2025, with Germany and France the largest markets. Assuming 50% yield from gutted weight to product weight, the European market consumed 165,000 tonnes product weight of smoked salmon in 2025.

Smoked consumption in EU+UK 2016-2025E

Secondary Processing (VAP)

European smoked salmon producers (2025E)

The ten largest producers of smoked salmon in Europe are estimated to have a joint market share of more than 60%. The production is mainly carried out in Poland, France, the UK, the Baltic states and the Netherlands.

Mowi produces its smoked salmon in Poland (Ustka), UK (Rosyth), France (Landivisiau), Belgium (Oostende) and Turkey (Istanbul), and its main markets are Germany, France, Italy and Benelux. After the acquisition of Morpol in 2013, Mowi became the largest producer of smoked salmon. Labeyrie is the second largest and sells most of its products to France, and has also significant sales to the UK, Spain, Italy and Belgium.

Estimated Annual Raw Material - Tonnes HOG			
70 - 90 000	20 - 40 000	5 - 20 000	
Mowi Consumer Products (PL-FR-BE-UK-TR)	Labeyrie (FR-UK) Milarex (PL)	Norvelita (LT) Mer Alliance (FR-PL) Lerøy (NL-SE-NO) Foppen (NL) Suempol (PL) Delpeyrat (FR)	Martiko (ES) Young's Seafood (UK) Moulin de la Marche (FR) Viciunai (LT) Zalmhuys Van Wijnen (NL) Krone Fisch (DE)

Secondary Processing (VAP)

14.4 Branding and product innovation

Consumer preferences and purchasing behaviour are changing, with greater emphasis on health, convenience, sustainability and product transparency. At the same time, consumers increasingly expect products to be tailored to different occasions, formats and local tastes. This creates an opportunity for branding and product innovation to differentiate salmon beyond price and origin.

Mowi's branding strategy puts the consumer at the centre of product innovation with a goal of de-commoditising the salmon category. Since the MOWI brand launch in 2019, the MOWI brand has experienced strong growth and has become the largest global salmon brand. In total the MOWI brand is now present in 26 countries. Based on market trends and evolving consumer habits, Mowi develops products ranging from fresh cuts, coated and smoked salmon, and specialty products to ready meals and on-the-go formats. By adapting products to local tastes and cuisines, Mowi creates new consumption occasions, broadens the use of salmon and increases consumption frequency, particularly in markets where salmon is not traditionally part of the local diet.

Appendix

Appendix

	Atlantic salmon
Live fish	100%
Loss of blood/starving	6%
Harvest weight / Round bled fish (wfe)	94%
Offal	10%
Gutted fish, approx. (HOG)	84%
Head, approx.	7%
Head off, gutted	77%
Fillet (skin on)	56–64%
C-trim (skin on)	60%
Fillet (skin off)	47–56%

Net weight^{52F}

Weight of a product at any stage (GWT, fillet, portions). Only the weight of the fish part of the product (excl. ice or packaging), but including other ingredients in VAP

Primary processing

Gutted Weight Equivalent (GWT) / Head on Gutted (HOG)

Secondary processing

Any value-added processing beyond GWT

Biomass

The total weight of live fish, where number of fish is multiplied by an average weight

Ensilage

Salmon waste from processing with added acid

BFCR

IB feed stock + feed purchase – UB feed stock
Kg produced – weight on smolt release

EFCR

IB feed stock + feed purchase – UB feed stock
Kg produced – mortality in Kg – weight on smolt release

Price Notifications

Sitagri Salmon Index (FCA Oslo) – Head on gutted from Norway (weighted average superior quality)

FOB Miami – fillets from Chile (3–4 lb)

FOB Seattle – whole fish from Canada (10–12 lb)

Source: Kontali Analyse

Appendix

Price indices vs. FOB packing plant.

Norwegian Sitagri Salmon Index - Selling price for superior gutted, fresh salmon iced and packed in boxes - FCA Oslo

Sitagri Salmon Index - Freight to Oslo - Terminal Cost = Selling price farmers FOB packing plant (sup/ord)	} ~1,50 NOK
---	-------------

Urner Barry FOB Miami - Chilean atlantic salmon fillets, PBO, d-trim delivered FOB Miami

UB - See text below** = Selling price farmers FOB packing plant

Urner Barry FOB Seattle - West Coast atlantic salmon - whole - fresh delivered FOB Seattle

FOB Seattle - Freight (~8-10 cent/lb) = Selling price farmers FOB packing plant

Several price indices for salmon are publicly available. The two most important providers of such statistics for Norwegian salmon are Sitagri/Fish Pool and Statistics Norway (SSB). Sitagri Salmon Index (Sisalmoni) is a 100% spot-based price, Fish Pool is primarily a forward price, and SSB is a mix of spot and contract prices. Urner Barry in the US provides a spot reference price for Chilean salmon in Miami and Canadian salmon in Seattle and Boston/New York.

In Norway, using Sisalmoni, the farmer's FOB packing plant price is found by deducting freight costs from the farm to Oslo and the terminal cost (~1.50 NOK).

Calculating Urner Barry – Chilean fillets back to GWT plant is more extensive. It can be done by using prices for 3–4 lb and adjusting for size mix share, trucking, handling and customs, and trade margin. Additional adjustments vary over time, including premium fish share (~90%), reduced price of downgraded fish (~30%), airfreight (USD 1.40–1.60/kg) and GWT-to-fillet yield (60–70%).

Source: Nasdaq, NOS/FHL, SSB, Norwegian Seafood Council, Urner Barry, Kontali Analyse

Appendix

Historic acquisitions and divestments

In Norway there have been 'countless' mergers between companies over the last decade. The list below shows only some of the larger ones in transaction value. In Scotland consolidation has also been very frequent. In Chile, there have been several acquisitions over the last two years. Canada's industry has been extensively consolidated with a few large players and some small companies.

See table on the next page.

2015	Thompson Bros Salmon - Sold to Cooke Aquaculture	2019	Cabo Pilar aquired by Nova Austral (4 licenses)		
2016	Balta Island Seafare - Sold to Cooke Aquaculture	2022	Cargill acquired 24,5% of Multi X, and Mitsu increased its share to 24,5%. Multiexport Foods remains the largets shareholder with 51% ownership		
2019	The Scottish Salmon Company aquired by Bakkafrost	2025	Nissui aquires Pescara Yadran and merges the company with their current daughter company Salmenes Antarctica		
2021	Grieg Seafood Hjaltland UK Ltd sold to Scottish Sea Farms (owned by Salmar and Lerøy Seafood				
2022	Mowi aquired Wester Ross Fisheries in Scotland				

Appendix

Breeding

Broodstock

- Bred on selected characteristics, e.g., growth, disease resistance, maturation, colour

Spawning and fertilization

- Eggs stripped from females and mixed with milt

Eyed eggs

- After 25-30 days fertilized eggs show "eyes". The development is depending on temp. 5000 eggs/liter

Alevins:

- Small (<2.5 cm). Yolk sack providing first stage nutrition. When absorbed, the fish start feeding

Fry par:

- Start feeding of small fish. Temp 12-14 °C. Fish is growing in FW sites to around 60-100g. Vaccination and grading important.

Smolt

Smolt:

- The smolt phase is a critical stage in the life cycle for salmon. It refers to the period when salmon undergo physiological changes that enable them to adapt from freshwater to saltwater environments (smoltification)
- A smolt is produced over a period of 8-12 months from startfeeding to a mature smolt weighing 150-250g. In recent years there has been made large investments in postsmolt
- Postsmolt production is referred to as smolt weighing between 250g to 1000g.
- The purpose of postsmolt is to accelerate the growth of salmon and reduce time in sea. This reduces exposure to sea lice, disease, and allows farmers to harvest the fish and bring them to market more quickly.

Feed

Feed

- Salmon are fed a specialized diet to promote healthy growth and development.
- The feed consists of a combination of fishmeal, fish oil, and other ingredients that provide essential nutrients such as proteins, fats, vitamins and minerals

Seawater

Seawater

- After the smolt phase, the salmon is transferred from freshwater to seawater tanks or pens located in sheltered coastal areas.
- Further, they are acclimated to saltwater conditions and allowed to grow further
- The net pens or tanks are designed to provide a controlled environment while allowing for the circulation of seawater, which provides oxygen and removes waste.

Harvesting

Harvesting

- When the farmed salmon reach their desired size (>4.5kg), they are ready for harvesting.
- Harvesting methods can vary but often involve the use of nets or harvesting systems that allow the fish to be efficiently collected from the net pens or tanks.
- The fish are carefully handled to minimize stress and maintain product quality

Processing

Processing

- After harvesting, the salmon are transported to processing facilities.
- The processing phase involves several steps, including cleaning, gutting, and removing the fish heads. The fish are then typically filleted and inspected for quality.
- Additional steps may include smoking, freezing or packaging the fish for distribution

Products & Customer

Products & customers

- The processed salmon products are packaged and distributed to various customers such as retailers, restaurants, and seafood markets.
- The products can range from fresh or frozen fillets to smoked salmon, salmon steaks, or value-added products like salmon burgers or sushi-grade portions.
- Customers may include individual consumers or businesses that incorporate salmon into their menus or sell it directly to end consumers.

Appendix

The history of MOWI

2025	Mowi takes full ownership of Nova Sea in Norway
2024	Recognised as the world's most sustainable animal protein producer for the sixth consecutive year
2022	Mowi enters Iceland with the acquisition of 51.28% of Arctic Fish
2021	Mowi 4.0 digital strategy is launched
2020	Self-sufficient for feed in Europe
2019	MOWI brand is launched
2018	The company once again becomes Mowi
2017–18	Acquires Gray Aqua Group and Northern Harvest, and establishes Mowi Canada East
2016	Enters joint venture with Deep Sea Supply to build, own and operate aquaculture vessels
2013	Acquires Morpol
2012	Feed division is established
2006	PanFish acquires Marine Harvest
2005	Marine Harvest and Stolt Sea Farm merge PanFish acquires Fjord Seafood John Fredriksen acquires PanFish
2000	Nutreco acquires Hydro Seafood. New company name: Marine Harvest
1999	Nutreco acquires the Scottish farming operations started by Unilever
1998	Mowi is discontinued as a company name Hydro Seafood has sites in Norway, Scotland and Ireland
1996	Hydro Seafood acquires Frøya holding
1990	Hydro Seafood registered 25 June Restructuring and consolidation of the industry starts
1985	Hydro increases its holding to 100%
1983	Mowi buys GSP in Scotland and Fanad in Ireland
1975	Mowi becomes a recognised brand
1969	Hydro increases its holding to 50%
1965	Mowi starts working with salmon in Norway
1964	The adventure of Mowi begins

Appendix

Mowi

Mowi is the world's largest producer of farm-raised salmon measured by both volume and turnover. We offer seafood products to more than 70 countries, are represented in 26 countries and employ 11 700 people. Mowi is organised into three business areas: Feed, Farming and Sales & Marketing.

Total revenue for Mowi in 2025 was MEUR 5,729 and the harvest quantity of Atlantic salmon was 558,870 tonnes (GWT), equivalent to a global market share of approximately 20%.
